WEBVTT

- 1 00:00:00.280 --> 00:00:01.760 <v Man>Good afternoon, everybody.</v>
- 2 00:00:01.760 --> 00:00:03.410 Good morning, Professor Holbrook.
- $3~00:00:04.520 \dashrightarrow 00:00:07.850$ Today I'm honored to introduce Professor Andrew Holbrook.
- $4~00:00:07.850 \dashrightarrow 00:00:11.460$ So professor Holbrook earned his bachelor's from UC Berkeley
- 5 00:00:11.460 --> 00:00:14.033 and a statistics masters and PhD from UC Irvine.
- $6\ 00:00:15.170 --> 00:00:16.930$ His research touches a number of areas
- $7\ 00:00:16.930 \longrightarrow 00:00:18.460$ of biomedical interests,
- $8~00:00:18.460 \longrightarrow 00:00:20.973$ including Alzheimer's and epidemiology.
- $9~00:00:22.180 \longrightarrow 00:00:23.690$ He's currently an assistant professor
- $10\ 00:00:23.690 \longrightarrow 00:00:27.280$ of biostatistics at UCLA, where he teaches their advanced
- $11\ 00:00:27.280 \longrightarrow 00:00:28.610$ basic computer course.
- 12 00:00:28.610 --> 00:00:30.000 And he's the author of several pieces
- $13\ 00:00:30.000 \longrightarrow 00:00:32.290$ of scientific software.
- $14\ 00:00:32.290 \longrightarrow 00:00:37.090$ All of it, I think, is he's very fond of parallelization,
- $15\ 00{:}00{:}37.090$ --> $00{:}00{:}40.330$ and he also has a package including one on studying
- 16 00:00:40.330 --> 00:00:43.880 Hawkes processes, which he's going to tell us...
- $17\ 00{:}00{:}43.880 \to 00{:}00{:}45.990$ Well, he's gonna tell us about the biological phenomenon
- $18\ 00:00:45.990 \longrightarrow 00:00:48.012$ and what's going on today.
- $19\ 00:00:48.012 \longrightarrow 00:00:50.493$ So Professor Holbrook, thank you so much.
- 20 00:00:51.500 --> 00:00:52.761 <-> Okay, great.</v>
- 21 00:00:52.761 --> 00:00:57.170 Thank you so much for the kind invitation,
- $22\ 00:00:57.170 --> 00:01:01.990$ and thanks for having me this morning slash afternoon.
- 23 00:01:01.990 --> 00:01:05.894 So today I'm actually gonna be kind of trying to present

- 24~00:01:05.894 --> 00:01:10.270 more of a high level talk that's gonna just focus on
- $25~00:01:10.270 \longrightarrow 00:01:13.610$ a couple of different problems that have
- $26\ 00:01:13.610 \longrightarrow 00:01:18.140$ come up when modeling Hawkes processes
- $27\ 00:01:18.140 --> 00:01:20.700$ for public health data, and in particular
- $28\ 00:01:20.700 --> 00:01:22.563$ for large scale public health data.
- $29\ 00:01:23.920 \longrightarrow 00:01:27.630$ So, today I'm interested in spatiotemporal data
- $30~00:01:27.630 \dashrightarrow 00:01:29.880$ in public health, and this can take a number
- $31\ 00:01:29.880 \longrightarrow 00:01:31.053$ of different forms.
- $32\ 00{:}01{:}32.680$ --> $00{:}01{:}37.680$ So a great example of this is in Washington D.C.
- $33\ 00:01:38.500 \longrightarrow 00:01:41.950$ Here, I've got about 4,000 gunshots.
- $34\ 00{:}01{:}41.950 --> 00{:}01{:}43.530$ You'll see this figure again,
- $35\ 00:01:43.530 \longrightarrow 00:01:46.160$ and I'll explain the colors to you
- $36\ 00:01:46.160 \longrightarrow 00:01:48.640$ and everything like that.
- $37\ 00:01:48.640 --> 00:01:52.930$ But I just want you to see that in the year 2018 alone,
- $38~00{:}01{:}52.930 \dashrightarrow 00{:}01{:}56.890$ there were 4,000 gunshots recorded in Washington DC.
- $39\ 00{:}01{:}56.890 \dashrightarrow 00{:}02{:}01.350$ And this is just one example of really a gun violence
- $40~00:02:01.350 \dashrightarrow 00:02:03.923$ problem in the U S of epidemic proportions.
- $41\ 00{:}02{:}07.483 \dashrightarrow 00{:}02{:}09.510$ But spatiotemporal public health data
- $42\ 00:02:09.510 \longrightarrow 00:02:11.210$ can take on many forms.
- $43\ 00:02:11.210$ --> 00:02:16.210 So here, for example, I have almost almost 3000 wild fires
- $44\ 00:02:18.290 \longrightarrow 00:02:22.543$ in Alaska between the years, 2015 and 2019.
- $45~00:02:23.810 \longrightarrow 00:02:28.720$ And this is actually just one piece of a larger
- $46\ 00:02:30.070 \longrightarrow 00:02:32.363$ trend that's going on in the American west.
- $47\ 00:02:34.810 \dashrightarrow 00:02:39.400$ And then finally, another example spatiotemporal public
- $48\ 00:02:39.400 --> 00:02:43.720$ health data is, and I believe that we don't need to spend

- 49 00:02:43.720 --> 00:02:45.650 too much time on this motivation,
- 50 00:02:45.650 --> 00:02:48.180 but it's the global spread of viruses.
- 51~00:02:48.180 --> 00:02:52.220 So for example, here, I've got 5,000 influenza cases
- 52 00:02:52.220 --> 00:02:56.290 recorded throughout, through 2000 to 2012.
- 53 00:02:57.750 --> 00:02:59.590 So if I want to model this data,
- $54~00:02:59.590 \longrightarrow 00:03:02.210$ what I'm doing is I'm modeling event data.
- $55~00:03:02.210 \longrightarrow 00:03:06.417$ And one of the classic models for doing so
- $56\ 00:03:06.417 \longrightarrow 00:03:11.417$ is really the canonical stochastic process here,
- $57\ 00{:}03{:}11.720 \dashrightarrow 00{:}03{:}14.240$ in this context is, is the Poisson process.
- $58~00{:}03{:}14.240 \dashrightarrow 00{:}03{:}17.840$ And I hope that you'll bear with me if we do just a little
- 59 00:03:17.840 --> 00:03:21.410 bit of review for our probability 101.
- $60~00:03:21.410 \dashrightarrow 00:03:23.810$ But we say that accounting process
- $61\ 00:03:23.810 \longrightarrow 00:03:27.659$ is a homogeneous Poisson process, point process
- $62\ 00:03:27.659$ --> 00:03:32.030 with rate parameter, excuse me, parameter lambda,
- $63\ 00:03:32.030 \longrightarrow 00:03:34.160$ which is greater than zero.
- $64\ 00:03:34.160 --> 00:03:37.823$ If this process is always equal to zero at zero,
- 65 00:03:38.700 --> 00:03:42.780 if it's independent increments, excuse me,
- 66 00:03:42.780 --> 00:03:46.103 if it's increment over non-overlapping intervals
- $67\ 00:03:47.720 --> 00:03:49.880$ are independent random variables.
- 68 00:03:49.880 --> 00:03:52.088 And then finally, if it's increments
- $69\ 00:03:52.088 \longrightarrow 00:03:57.020$ are Poisson distributed with mean given
- $70\ 00:03:57.020 --> 00:03:59.510$ by that rate parameter lambda,
- $71\ 00:03:59.510 \longrightarrow 00:04:01.943$ and then the difference in the times.
- 72 00:04:03.890 --> 00:04:05.230 So we can make this model
- $73\ 00:04:06.866 \longrightarrow 00:04:09.370$ just a very little bit more complex.
- $74\ 00:04:09.370 \longrightarrow 00:04:13.450$ We can create an inhomogeneous Poisson point process,
- 75 00:04:13.450 --> 00:04:15.810 simply by saying that that rate parameter
- $76\ 00:04:15.810 \longrightarrow 00:04:19.930$ is no longer fixed, but itself is a function

- $77\ 00:04:19.930 \longrightarrow 00:04:21.850$ over the positive real line.
- 78 00:04:21.850 --> 00:04:24.010 And here everything is the exact same,
- 79 00:04:24.010 --> 00:04:27.620 except now we're saying that it's increments,
- $80\ 00:04:27.620 \longrightarrow 00:04:29.930$ it's differences over two different time periods
- 81 00:04:29.930 \rightarrow 00:04:34.930 are Poisson distributed, where now the mean is simply given
- $82\ 00:04:35.270 \longrightarrow 00:04:39.840$ by the definite integral over that interval.
- $83\ 00:04:39.840 \longrightarrow 00:04:41.903$ So we just integrate that rate function.
- 84 00:04:44.370 --> 00:04:45.499 Okay.
- $85\ 00:04:45.499 --> 00:04:47.800$ So then how do we choose our rate function for the problems
- 86 00:04:47.800 --> 00:04:49.370 that we're interested in?
- $87\ 00:04:49.370 \longrightarrow 00:04:53.410$ Well, if we return to say the gun violence example,
- $88\ 00{:}04{:}53.410 \dashrightarrow 00{:}04{:}58.220$ then it is plausible that at least sometimes some gun
- $89~00:04:58.220 \longrightarrow 00:05:02.630$ violence might precipitate more gun violence.
- $90~00:05:02.630 \longrightarrow 00:05:07.513$ So here we would say that having observed an event,
- $91\ 00:05:09.050$ --> 00:05:11.730 having observed gunshots at a certain location
- $92\ 00:05:11.730 \longrightarrow 00:05:14.820$ at a certain time, we might expect that the probability
- $93\ 00:05:14.820$ --> 00:05:19.820 of observing gunshots nearby and soon after is elevated.
- $94\ 00:05:23.480$ --> 00:05:27.830 and the same could plausibly go for wildfires as well.
- 95 00:05:27.830 --> 00:05:32.830 It's that having observed a wildfire in a certain location,
- $96~00:05:33.400 \longrightarrow 00:05:38.077$ this could directly contribute to the existence
- $97\ 00:05:39.000 \longrightarrow 00:05:42.310$ or to the observation of other wildfires.
- 98 00:05:42.310 --> 00:05:45.350 So for example, this could happen by natural means.
- 99 00:05:45.350 --> 00:05:48.763 So we could have embers that are blown by the wind.

- $100\ 00:05:51.052 --> 00:05:53.850$ or there could be a human that is in fact
- $101\ 00{:}05{:}53.850 \dashrightarrow 00{:}05{:}57.423$ causing these wildfires, which is also quite common.
- $102\ 00:06:00.620 \longrightarrow 00:06:02.900$ And then it's not a stretch at all
- $103\ 00:06:02.900 \longrightarrow 00:06:07.540$ to believe that viral observation,
- $104\ 00:06:07.540 \longrightarrow 00:06:11.870$ so a child sick with influenza could precipitate
- $105\ 00:06:11.870 --> 00:06:16.190$ another child that becomes sick with influenza
- $106\ 00:06:16.190 \longrightarrow 00:06:18.993$ in the same classroom and perhaps on the next day.
- $107\ 00{:}06{:}22.778 \dashrightarrow 00{:}06{:}27.440$ So then, the solution to building this kind of dynamic into
- 108~00:06:27.440 --> 00:06:32.440 an in homogeneous Poisson process is simply to craft
- $109\ 00{:}06{:}32.790 \dashrightarrow 00{:}06{:}36.700$ the rate function in a way that is asymmetric in time.
- $110\ 00:06:36.700$ --> 00:06:40.523 So here is just a regular temporal Hawkes process.
- $111\ 00:06:43.418 --> 00:06:48.010$ And what we do is we divide this rate function, lambda T,
- $112\ 00:06:48.010 \longrightarrow 00:06:50.810$ which I'm showing you in the bottom of the equation,
- $113\ 00:06:50.810 \longrightarrow 00:06:55.430$ into a background portion which is here.
- $114\ 00{:}06{:}55.430 \dashrightarrow 00{:}06{:}58.923$ I denote nu, and this nu can be a function itself.
- 115 00:07:00.030 --> 00:07:04.090 And then we also have this self excitatory component C of T.
- 116 00:07:04.090 --> 00:07:08.110 And this self excitatory component for time T,
- $117\ 00{:}07{:}08.110 {\: --> \:} 00{:}07{:}13.110$ it depends exclusively on observations
- $118\ 00:07:13.160 \longrightarrow 00:07:15.880$ that occur before time T.
- $119\ 00:07:16.832 \longrightarrow 00:07:21.832$ So each tn, where tn is less than T,
- $120\ 00:07:22.020 --> 00:07:25.000$ are able to contribute information
- $121\ 00:07:25.000 \longrightarrow 00:07:27.083$ in some way to this process.
- 122 00:07:28.550 --> 00:07:31.970 And typically G is our triggering function.

- 123 00:07:31.970 --> 00:07:34.803 G is non increasing.
- $124\ 00:07:36.961 \longrightarrow 00:07:39.520$ And then the only other thing that we ask
- $125\ 00:07:39.520 \longrightarrow 00:07:42.330$ is that the different events contribute
- $126\ 00:07:42.330 \longrightarrow 00:07:44.960$ in an additive manner to the rate.
- $127\ 00{:}07{:}44.960 \dashrightarrow 00{:}07{:}48.840$ So here, we've got the background rate in this picture,
- $128\ 00:07:48.840 \longrightarrow 00:07:50.480$ We have observation T1.
- $129\ 00:07:50.480 \longrightarrow 00:07:51.993$ The rate increases.
- $130\ 00:07:53.020 \longrightarrow 00:07:54.640$ It slowly decreases.
- $131\ 00:07:54.640 \dashrightarrow 00:07:57.350$ We have another observation, the rate increases.
- $132\ 00:07:57.350 \longrightarrow 00:07:59.900$ And what you see is actually that after T1,
- $133\ 00:07:59.900 \longrightarrow 00:08:04.330$ we have a nice little bit of self excitation as it's termed,
- $134\ 00:08:04.330 \longrightarrow 00:08:07.063$ where we observe more observations.
- $135\ 00{:}08{:}08{:}08{:}940 \dashrightarrow 00{:}08{:}12.730$ This model itself can be made just a little bit more complex
- $136\ 00:08:12.730 \longrightarrow 00:08:14.430$ if we add a spatial component.
- $137\ 00:08:14.430 \longrightarrow 00:08:18.350$ So here now, is the spatiotemporal Hawkes process
- $138\ 00:08:18.350 \longrightarrow 00:08:22.440$ where I'm simply showing you the background process,
- $139\ 00:08:22.440 \longrightarrow 00:08:25.600$ which now I'm allowing to be described
- $140\ 00:08:25.600 \longrightarrow 00:08:29.000$ by a rate function over space.
- $141\ 00:08:29.000 \longrightarrow 00:08:32.260$ And then, we also have the self excitatory component,
- 142 00:08:32.260 --> 00:08:34.890 which again, although it also involves
- $143\ 00:08:34.890 \longrightarrow 00:08:36.780$ a spatial component in it,
- $144\ 00:08:36.780 \longrightarrow 00:08:39.550$ it still has this asymmetry in time.
- $145\ 00:08:39.550 \longrightarrow 00:08:42.140$ So in this picture, we have these,
- $146\ 00:08:42.140 \longrightarrow 00:08:44.410$ what are often called immigrant events
- $147\ 00:08:44.410 \longrightarrow 00:08:47.543$ or parent events in black.
- 148 00:08:48.590 --> 00:08:50.250 And then we have the child events,

 $149\ 00:08:50.250$ --> 00:08:53.230 the offspring from these events described in blue.

 $150\ 00{:}08{:}53.230 \to 00{:}08{:}58.090$ So this appears to a pretty good stochastic process model,

 $151\ 00{:}08{:}58.090 \to 00{:}09{:}02.210$ which is not overly complex, but is simply complex enough

 $152\ 00:09:02.210 \longrightarrow 00:09:04.783$ to capture contagion dynamics.

 $153\ 00:09:08.240 --> 00:09:11.440$ So for this talk, I'm gonna be talking about some major

 $154\ 00:09:11.440 \dashrightarrow 00:09:16.440$ challenges that are confronting the really data analysis

 $155\ 00:09:16.540 \longrightarrow 00:09:18.820$ using the Hawkes process.

 $156\ 00:09:18.820 --> 00:09:22.920$ So very applied in nature, and these challenges persist

 $157\ 00:09:22.920 \longrightarrow 00:09:25.760$ despite the use of a very simple model.

 $158\ 00:09:25.760 \dashrightarrow 00:09:28.840$ So basically, all the models that I'm showing you today

159 00:09:28.840 --> 00:09:32.640 are variations on this extremely simple model,

 $160\ 00:09:32.640 \longrightarrow 00:09:35.360$ as far as the Hawkes process literature goes.

 $161\ 00:09:35.360 --> 00:09:39.810$ So we assume an exponential decay triggering function.

162 00:09:39.810 --> 00:09:41.930 So here in this self excitatory component,

 $163\ 00:09:41.930 \longrightarrow 00:09:46.892$ what this looks like is the triggering function

 $164\ 00:09:46.892 \longrightarrow 00:09:51.892$ is simply the exponentiation of negative omega,

 $165\ 00:09:52.470 \longrightarrow 00:09:56.210$ where one over omega is some sort of length scale.

 $166\ 00:09:56.210 \longrightarrow 00:09:58.210$ And then we've got T minus tn.

 $167\ 00:09:58.210 --> 00:10:01.050$ Again, that difference between a T

 $168\ 00:10:01.050 \longrightarrow 00:10:04.720$ and preceding event times.

 $169\ 00:10:04.720 --> 00:10:06.500$ And then we're also assuming Gaussian kernel

 $170\ 00:10:06.500 \longrightarrow 00:10:08.550$ spatial smoothers, very simple.

 $171\ 00{:}10{:}08.550 \dashrightarrow 00{:}10{:}11.700$ And then finally, another simplifying assumption

172 00:10:11.700 --> 00:10:14.170 that we're making is separability.

 $173\ 00:10:14.170 \longrightarrow 00:10:19.170$ So, in these individual components of the rate function,

 $174\ 00:10:20.061$ --> 00:10:24.770 we always have separation between the temporal component.

 $175\ 00{:}10{:}24.770 \dashrightarrow 00{:}10{:}27.760$ So here on the left, and then the spatial component

 $176\ 00:10:27.760 \longrightarrow 00:10:30.473$ on the right, and this is a simplifying assumption.

 $177\ 00:10:34.230 \longrightarrow 00:10:37.300$ So what are the challenges that I'm gonna present today?

 $178\ 00:10:37.300 \longrightarrow 00:10:42.300$ The first challenge is big data because when we are modeling

 $179\ 00:10:42.480 \dashrightarrow 00:10:46.430$ many events, what we see is the computational complexity

180 00:10:46.430 --> 00:10:48.423 of actually carrying out inference,

181 00:10:50.909 --> 00:10:53.900 whether using maximum likelihood or using say,

182 00:10:53.900 --> 00:10:55.550 Markov chain Monte Carlo,

183 00:10:55.550 --> 00:10:57.430 well, that's actually gonna explode quickly,

 $184\ 00:10:57.430 \longrightarrow 00:10:59.320$ the computational complexity.

 $185\ 00:10:59.320 \longrightarrow 00:11:01.760$ Something else is the spatial data precision.

 $186~00{:}11{:}01.760 \dashrightarrow 00{:}11{:}04.323$ And this is actually related to big data.

 $187\ 00:11:06.060 \longrightarrow 00:11:07.990$ As we accrue more data,

188 00:11:07.990 --> 00:11:10.930 it's harder to guarantee data quality,

189 00:11:10.930 --> 00:11:14.770 but then also the tools that I'm gonna offer up to actually

 $190\ 00{:}11{:}14.770 \dashrightarrow 00{:}11{:}18.440$ deal with poor spatial data precision are actually

191 00:11:18.440 --> 00:11:21.350 gonna also suffer under a big data setting.

192 00:11:21.350 --> 00:11:24.060 And then finally, big models.

 $193~00{:}11{:}24.060 \dashrightarrow 00{:}11{:}26.670$ So, you know, when we're trying to draw very specific

 $194\ 00{:}11{:}26.670 \dashrightarrow 00{:}11{:}30.750$ scientific conclusions from our model, then what happens?

- 195 00:11:30.750 --> 00:11:32.580 And all these data, excuse me,
- 196 00:11:32.580 --> 00:11:34.380 all these challenges are intertwined,
- $197\ 00:11:34.380 \longrightarrow 00:11:35.830$ and I'll try to express that.
- 198 00:11:38.990 --> 00:11:43.100 Finally today, I am interested in scientifically
- $199\ 00:11:43.100 \longrightarrow 00:11:46.300$ interpretable inference.
- 200 00:11:46.300 --> 00:11:48.470 So, I'm not gonna talk about prediction,
- 201 00:11:48.470 --> 00:11:50.720 but if you have questions about prediction,
- $202\ 00:11:50.720 \longrightarrow 00:11:52.530$ then we can talk about that afterward.
- $203\ 00:11:52.530 \longrightarrow 00:11:53.363$ I'm happy too.
- 204 00:11:57.450 --> 00:11:58.283 Okay.
- 205 00:11:58.283 --> 00:11:59.840 So I've shown you this figure before,
- $206\ 00:11:59.840 \longrightarrow 00:12:01.760$ and it's not the last time that you'll see it.
- $207\ 00:12:01.760 \longrightarrow 00:12:04.780$ But again, this is 4,000 gunshots in 2018.
- $208\ 00:12:04.780 --> 00:12:07.420$ This is part of a larger dataset that's made available
- $209\ 00:12:07.420 \longrightarrow 00:12:10.693$ by the Washington DC Police Department.
- 210 00:12:11.680 --> 00:12:14.930 And in fact, from 2006 to 2018,
- $211\ 00:12:14.930 \longrightarrow 00:12:19.560$ we have over 85,000 potential gunshots recorded.
- 212 00:12:19.560 --> 00:12:20.580 How are they recorded?
- $213\ 00{:}12{:}20.580 \dashrightarrow 00{:}12{:}23.820$ They're recorded using the help of an acoustic gunshot
- $214\ 00:12:23.820 \longrightarrow 00:12:27.910$ locator system that uses the actual acoustics
- $215\ 00:12:27.910 \longrightarrow 00:12:31.570$ to triangulate the time and the location
- $216\ 00:12:31.570 \longrightarrow 00:12:33.913$ of the individual gunshots.
- $217\ 00{:}12{:}35.030 \dashrightarrow 00{:}12{:}39.730$ So in a 2018 paper, Charles Loeffler and Seth Flaxman,
- $218\ 00{:}12{:}39.730 \dashrightarrow 00{:}12{:}44.217$ they used a subset of this data in a paper entitled
- 219 00:12:44.217 --> 00:12:45.690 "Is Gun Violence Contagious?"
- $220\ 00{:}12{:}45.690$ --> $00{:}12{:}48.730$ And they in fact apply to Hawkes process model
- 221 00:12:48.730 --> 00:12:50.700 to try to determine their question,

- $222\ 00:12:50.700 \longrightarrow 00:12:52.150$ the answer to their question.
- 223 00:12:53.170 --> 00:12:54.800 But in order to do, though,
- $224\ 00:12:54.800 \longrightarrow 00:12:56.870$ they had to significantly subset.
- $225\ 00:12:56.870 \longrightarrow 00:12:59.690$ They took roughly 10% of the data.
- 226 00:12:59.690 --> 00:13:01.990 So the question is whether their conclusions,
- 227 00:13:01.990 --> 00:13:06.070 which in fact work yes to the affirmative,
- $228\ 00{:}13{:}06.070 \dashrightarrow 00{:}13{:}10.800$ they were able to detect this kind of contagion dynamics.
- 229 00:13:10.800 --> 00:13:14.000 But the question is, do their results hold
- 230 00:13:14.000 --> 00:13:16.137 when we analyze the complete data set?
- 231 00:13:18.130 --> 00:13:20.450 So for likelihood based inference,
- 232 00:13:20.450 \rightarrow 00:13:25.340 which we're going to need to use in order to learn.
- $233\ 00{:}13{:}25.340 \dashrightarrow 00{:}13{:}28.543$ in order to apply the Hawkes process to real-world data.
- $234\ 00:13:30.350 \longrightarrow 00:13:34.200$ for the first thing to see is that the likelihood
- $235~00{:}13{:}34.200 \dashrightarrow 00{:}13{:}38.670$ takes on the form of an integral term on the left.
- $236\ 00:13:38.670 \longrightarrow 00:13:42.950$ And then we have a simple product of the rate function
- $237\ 00{:}13{:}42.950 \rightarrow 00{:}13{:}47.943$ evaluated at our individual events, observed events
- 238 00:13:49.880 --> 00:13:52.780 And when we consider the log likelihood,
- 239 00:13:52.780 --> 00:13:57.780 then it in fact will involve this term that I'm showing you
- 240 00:13:58.010 --> 00:14:00.410 on the bottom line, where it's the sum
- $241\ 00{:}14{:}00.410$ --> $00{:}14{:}04.030$ of the log of the, again, the rate function evaluated
- 242 00:14:04.030 --> 00:14:07.430 at the individual events. (background ringing)
- 243 00:14:07.430 --> 00:14:08.263 I'm sorry.
- $244\ 00:14:08.263 --> 00:14:10.260$ You might be hearing a little bit of the sounds
- $245\ 00{:}14{:}10.260 \dashrightarrow 00{:}14{:}14.110$ of Los Angeles in the background, and there's very little
- $246\ 00:14:14.110 \longrightarrow 00:14:16.460$ that I can do about Los Angeles.

- 247 00:14:16.460 --> 00:14:18.740 So moving on.
- $248\ 00:14:18.740 \longrightarrow 00:14:23.740$ So this summation in the log likelihood occurs.
- $249\ 00:14:24.800 \longrightarrow 00:14:27.640$ It actually involves a double summation.
- 250 00:14:27.640 --> 00:14:31.500 So it is the sum over all of our observations,
- $251\ 00:14:31.500 \longrightarrow 00:14:33.970$ of the log of the rate function.
- $252\ 00{:}14{:}33.970 \dashrightarrow 00{:}14{:}36.900$ And then, again, the rate function because of the very
- $253\ 00{:}14{:}36.900 \dashrightarrow 00{:}14{:}40.840$ specific form taken by the self excitatory component
- $254\ 00{:}14{:}40.840 \longrightarrow 00{:}14{:}43.973$ is also gonna involve this summation.
- $255\ 00{:}14{:}44.920$ --> $00{:}14{:}48.543$ So the upshot is that we actually need to evaluate.
- 256 00:14:49.380 --> 00:14:52.500 Every time we evaluate the log likelihood,
- 257 00:14:52.500 --> 00:14:57.500 we're going to need to evaluate N choose two,
- $258\ 00:14:59.110 --> 00:15:00.730$ where N is the number of data points.
- $259~00{:}15{:}00.730 \dashrightarrow 00{:}15{:}05.580$ N choose two terms, in this summation right here,
- $260~00{:}15{:}05.580 \dashrightarrow 00{:}15{:}07.930$ and then we're gonna need to sum them together.
- 261 00:15:09.300 --> 00:15:13.223 And then the gradient also features this,
- 262 00:15:15.790 --> 00:15:18.133 quadratic computational complexity.
- $263\ 00{:}15{:}20.700$ --> $00{:}15{:}23.120$ So the solution, the first solution that I'm gonna offer up
- $264\ 00:15:23.120 \longrightarrow 00:15:25.060$ is not a statistical solution.
- 265 00:15:25.060 --> 00:15:26.960 It's a parallel computing solution.
- $266\ 00{:}15{:}26.960 \dashrightarrow 00{:}15{:}31.240$ And the basic idea is, well, all of these terms that we need
- $267~00{:}15{:}31.240 \dashrightarrow 00{:}15{:}36.100$ to sum over, evaluate and sum over, let's do it all at once
- $268\ 00:15:36.100 \longrightarrow 00:15:38.083$ and thereby speed up our inference.
- $269\ 00:15:40.730 \longrightarrow 00:15:44.490\ I$ do so, using multiple computational tools.
- $270\ 00:15:44.490$ --> 00:15:49.490 So the first one is I use CP, they're just multicore CPUs.

 $271\ 00:15:50.380 --> 00:15:54.350$ These can have anywhere from two to 100 cores.

 $272\ 00:15:54.350 --> 00:15:58.360$ And then I combine this with something called SIMD,

 $273\ 00:15:58.360 --> 00:16:02.440$ single instruction multiple data, which is vectorization.

 $274\ 00:16:02.440 \longrightarrow 00:16:07.440$ So the idea, the basic idea is that I can apply a function,

 $275\ 00{:}16{:}08.960 \dashrightarrow 00{:}16{:}13.420$ the same function, the same instruction set to an extended

 $276\ 00:16:13.420 \longrightarrow 00:16:18.420$ register or vector of input data, and thereby speed up

277 00:16:19.950 --> 00:16:24.340 my computing by a factor that is proportional

278 00:16:24.340 --> 00:16:27.380 to the size of the vector that I'm evaluating

 $279\ 00:16:27.380 \longrightarrow 00:16:29.170$ my function over.

 $280\ 00:16:29.170 --> 00:16:32.970$ And then, I actually can do something better than this.

281 00:16:32.970 --> 00:16:35.030 I can use a graphic processing unit,

 $282\ 00:16:35.030$ --> 00:16:38.610 which instead of hundreds cores, has thousands of cores.

 $283\ 00:16:38.610 \longrightarrow 00:16:42.160$ And instead of SIMD, or it can be interpreted as SIMD,

 $284\ 00:16:42.160 \longrightarrow 00:16:45.420$ but Nvidia likes to call it a single instruction

 $285\ 00:16:45.420 --> 00:16:47.380$ multiple threads or SIMT.

 $286\ 00:16:47.380 \longrightarrow 00:16:50.040$ And here, what the major difference

287 00:16:50.040 --> 00:16:52.143 is the scale at which it's occurring.

 $288\ 00:16:54.180 --> 00:16:58.320$ And then, the other difference is that actually

 $289\ 00{:}16{:}58.320 \dashrightarrow 00{:}17{:}01.090$ individual threads or small working groups of threads

 $290\ 00:17:01.090 \longrightarrow 00:17:03.210$ on my GPU can work together.

 $291~00{:}17{:}03.210 \dashrightarrow 00{:}17{:}06.720$ So actually the tools that I have available are very complex

 $292\ 00{:}17{:}06.720 \dashrightarrow 00{:}17{:}09.540$ and a lot of need for care.

 $293\ 00:17:09.540 --> 00:17:13.430$ There's a lot of need to carefully code this up.

- 294~00:17:13.430 --> 00:17:17.760 The solution is not statistical, but it's very much
- 295 00:17:17.760 --> 00:17:19.400 an engineering solution.
- $296\ 00:17:19.400 \longrightarrow 00:17:23.640$ But the results are really, really impressive
- 297 00:17:23.640 --> 00:17:26.660 from my standpoint, because if I compare.
- 298~00:17:26.660 --> 00:17:31.660 So on the left, I'm comparing relative speed ups against
- $299~00:17:31.880 \dashrightarrow 00:17:36.880$ a very fast single core SIMD implementation on the left.
- $300\ 00{:}17{:}39.780 \longrightarrow 00{:}17{:}43.233$ So my baseline right here is the bottom of this blue curve.
- 301~00:17:44.220 --> 00:17:47.520 The X axis is giving me the number of CPU threads
- 302 00:17:47.520 --> 00:17:50.593 that I'm using, between one and 18.
- $303\ 00:17:51.930 --> 00:17:54.760$ And then, the top line is not using CPU threads.
- $304\ 00:17:54.760 --> 00:17:58.110$ So I just create a top-line that's flat.
- $305\ 00:17:58.110 \longrightarrow 00:18:00.680$ This is the GPU results.
- 306 00:18:00.680 --> 00:18:03.560 If I don't use SIMD, if I use non vectorized
- 307 00:18:03.560 --> 00:18:05.680 single core computing, of course, this is still
- $308\ 00:18:05.680 \longrightarrow 00:18:08.180$ pre-compiled C++ implementation.
- $309\ 00:18:08.180 \longrightarrow 00:18:10.950$ So it's fast or at least faster than R,
- $310\ 00:18:10.950 \longrightarrow 00:18:13.150$ and I'll show you that on the next slide.
- 311 00:18:13.150 --> 00:18:17.380 If I do that, then AVX is twice as fast.
- $312\ 00:18:17.380 \longrightarrow 00:18:19.593$ As I increased the number of cores,
- 313 00:18:20.815 --> 00:18:24.310 my relative speed up increases,
- $314\ 00:18:24.310 \longrightarrow 00:18:26.523$ but I also suffer diminishing returns.
- $315\ 00:18:28.160 \longrightarrow 00:18:31.230$ And then that is actually all these simulations
- $316\ 00:18:31.230 \longrightarrow 00:18:32.540$ on the left-hand plot.
- $317\ 00:18:32.540 \longrightarrow 00:18:34.380$ That's for a fixed amount of data.
- 318 00:18:34.380 --> 00:18:38.420 That's 75,000 randomly generated data points
- $319\ 00:18:38.420 \longrightarrow 00:18:41.520$ at each iteration of my simulation.

- $320\ 00{:}18{:}41.520$ --> $00{:}18{:}45.320$ But I can also just look at the seconds per evaluation.
- 321 00:18:45.320 --> 00:18:48.630 So that's my Y axis on the right-hand side.
- $322\ 00:18:48.630 \longrightarrow 00:18:52.910$ So ideally I want this to be as low as possible.
- $323~00{:}18{:}52.910 \dashrightarrow 00{:}18{:}55.520$ And then I'm increasing the number of data points
- $324\ 00:18:55.520 \longrightarrow 00:18:58.353$ on the Y axis, on the X axis, excuse me.
- $325\ 00:19:00.140 \longrightarrow 00:19:03.020$ And then as the number of threads that I use,
- 326 00:19:03.020 --> 00:19:04.890 as I increased the number of threads,
- $327\ 00:19:04.890 \longrightarrow 00:19:08.000$ then my implementation is much faster.
- $328\ 00:19:08.000 \dashrightarrow 00:19:11.600$ But again, you're seeing this quadratic computational
- 329 00:19:11.600 --> 00:19:14.010 complexity at play, right.
- $330\ 00:19:14.010 \longrightarrow 00:19:16.953$ All of these lines are looking rather parabolic.
- 331 00:19:18.100 --> 00:19:20.880 Finally, I go down all the way to the bottom,
- 332 00:19:20.880 --> 00:19:22.400 where I've got my GPU curve,
- 333 00:19:22.400 --> 00:19:24.670 again, suffering, computational complexity,
- $334\ 00:19:24.670 \longrightarrow 00:19:27.230$ which the quadratic computational complexity,
- $335\ 00{:}19{:}27.230 \dashrightarrow 00{:}19{:}30.560$ which we can't get past, but doing a much better job
- 336 00:19:30.560 --> 00:19:32.450 than the CPU computing.
- 337 00:19:32.450 --> 00:19:34.520 Now you might ask, well, you might say,
- $338\ 00:19:34.520 \dashrightarrow 00:19:37.870$ well, a 100 fold speed up is not that great.
- 339 00:19:37.870 --> 00:19:40.890 So I'd put this in perspective and say, well,
- $340\ 00:19:40.890 --> 00:19:45.450$ what does this mean for R, which I use every day?
- $341\ 00:19:45.450 \longrightarrow 00:19:48.920$ Well, what it amounts to,
- $342\ 00{:}19{:}48.920 \dashrightarrow 00{:}19{:}51.230$ and here, I'll just focus on the relative speed up
- $343\ 00:19:51.230 \longrightarrow 00:19:55.360$ over our implementation on the right.
- $344\ 00:19:55.360 \longrightarrow 00:19:59.423$ The GPU is reliably over 1000 times faster.

- $345~00{:}20{:}03.680$ --> $00{:}20{:}08.680$ So the way that Charles Loeffler and Seth Flaxman
- $346\ 00:20:12.420 \longrightarrow 00:20:16.170$ obtained a subset of their data was actually
- $347\ 00:20:16.170 \longrightarrow 00:20:17.993$ by thinning the data.
- $348\ 00{:}20{:}21.260 \dashrightarrow 00{:}20{:}23.840$ They needed to do so because of the sheer computational
- $349\ 00:20:23.840 --> 00:20:27.150$ complexity of using the Hawkes model.
- 350 00:20:27.150 --> 00:20:30.170 So, I'm not criticizing this in any way,
- 351 00:20:30.170 --> 00:20:33.910 but I'm simply pointing out why our results
- $352\ 00:20:33.910 --> 00:20:36.470$ using the full data set, differ.
- $353\ 00:20:36.470 \longrightarrow 00:20:39.538$ So on the left, on the top left,
- $354\ 00{:}20{:}39.538 \dashrightarrow 00{:}20{:}43.600$ we have the posterior density for the spatial length scale
- $355\ 00:20:43.600 \longrightarrow 00:20:45.600$ of the self excitatory component.
- 356 00:20:45.600 --> 00:20:47.600 And when we use the full data set,
- $357\ 00{:}20{:}47.600 \dashrightarrow 00{:}20{:}51.000$ then we believe that we're operating more at around 70
- $358\ 00{:}20{:}51.000 \dashrightarrow 00{:}20{:}56.000$ meters instead of the 126 inferred in the original paper.
- $359\ 00{:}20{:}56.480 \dashrightarrow 00{:}21{:}00.900$ So one thing that you might notice is our posterior
- $360\ 00{:}21{:}00.900 \longrightarrow 00{:}21{:}05.477$ densities are much more concentrated than in blue,
- $361\ 00:21:07.930 \longrightarrow 00:21:12.150$ than the original analysis in Salmon.
- 362 00:21:12.150 --> 00:21:13.970 And this of course makes sense.
- $363\ 00:21:13.970 \longrightarrow 00:21:16.673$ We're using 10 times the amount of the data.
- 36400:21:17.610 --> 00:21:20.360 Our temporal length scale is also meant,
- $365\ 00:21:20.360 \longrightarrow 00:21:24.070$ is also, we believe, much smaller, in fact.
- $366~00{:}21{:}24.070 \dashrightarrow 00{:}21{:}27.550$ So now it's down to one minute instead of 10 minutes.
- 367 00:21:27.550 --> 00:21:29.070 Again, this could be interpreted
- $368\ 00:21:29.070 \longrightarrow 00:21:31.540$ as the simple result of thinning.
- $369~00{:}21{:}31.540 \dashrightarrow 00{:}21{:}34.618$ And then finally, I just want to focus on this on

- $370\ 00:21:34.618 \longrightarrow 00:21:38.733$ the green posterior density.
- $371\ 00:21:40.972 \longrightarrow 00:21:43.772$ This is the proportion of events that we're interpreting
- $372\ 00{:}21{:}44.760 \dashrightarrow 00{:}21{:}49.760$ that arise from self excitation or contagion dynamics.
- $373~00{:}21{:}49.890 \dashrightarrow 00{:}21{:}54.890$ Experts believe that anywhere between 10 and 18% of gun
- 374 00:21:56.010 --> 00:21:59.380 violence events are retaliatory in nature.
- $375\ 00:21:59.380 \longrightarrow 00:22:04.380$ So actually our inference is kind of agreeing with,
- $376\ 00{:}22{:}06.960 \dashrightarrow 00{:}22{:}11.783$ it safely within the band suggested by the experts.
- 377 00:22:15.030 --> 00:22:17.590 Actually, another thing that we can do,
- $378\ 00:22:17.590 \longrightarrow 00:22:21.510$ and that also requires a pretty computationally.
- $379\ 00{:}22{:}21.510 \dashrightarrow 00{:}22{:}26.510$ So this is also quadratic computational complexity.
- 380 00:22:26.940 --> 00:22:30.110 Again, is post-processing.
- 381 00:22:30.110 --> 00:22:32.410 So if, for example, for individual events,
- $382\ 00:22:32.410 \longrightarrow 00:22:36.370$ we want to know the probability that the event arose
- 383 00:22:38.203 --> 00:22:41.050 from retaliatory gun violence,
- $384\ 00{:}22{:}41.050 \dashrightarrow 00{:}22{:}46.050$ then we could look at the self excitatory component
- $385\ 00:22:46.210$ --> 00:22:49.150 of the rate function divided by the total rate function.
- $386\ 00:22:49.150 \longrightarrow 00:22:51.220$ And then we can just look at the posterior
- $387\ 00:22:51.220 \longrightarrow 00:22:54.970$ distribution of this statistic.
- $388\ 00:22:54.970 \longrightarrow 00:22:58.415$ And this will give us our posterior probability
- $389\ 00:22:58.415 --> 00:23:03.415$ that the event arose from contagion dynamics at least.
- $390\ 00:23:03.930 \longrightarrow 00:23:05.790$ And you can see that we can actually observe
- $391\ 00:23:05.790 \longrightarrow 00:23:09.157$ a very wide variety of values.
- $392\ 00{:}23{:}22.740 \longrightarrow 00{:}23{:}27.740$ So the issue of big data is actually not gonna go away,

- $393\ 00:23:28.450 \longrightarrow 00:23:32.163$ as we move on to discussing spatial data precision.
- $394~00{:}23{:}33.290 \dashrightarrow 00{:}23{:}37.760$ Now, I'll tell you a little bit more about this data.
- $395\ 00:23:37.760 \longrightarrow 00:23:42.100$ All the data that we access is freely accessible online,
- $396\ 00:23:42.100 \longrightarrow 00:23:47.100$ is rounded to the nearest 100 meters
- $397\ 00:23:47.930 \longrightarrow 00:23:51.470$ by the DC Police Department.
- $398\ 00:23:51.470 \longrightarrow 00:23:56.313$ And the reason that they do this is for reasons of privacy.
- $399\ 00:23:57.740 \longrightarrow 00:24:00.820$ So one immediate question that we can ask is, well,
- $400\ 00{:}24{:}00.820$ --> $00{:}24{:}05.483$ how does this rounding actually affect our inference?
- 401 00:24:09.890 --> 00:24:12.590 Now we actually observed wildfires
- 402 00:24:12.590 --> 00:24:14.863 of wildly different sizes.
- 403 00:24:15.800 --> 00:24:18.770 And the question is, well, how does...
- 404 00:24:23.220 --> 00:24:27.520 If we want to model the spread of wildfires,
- $405\ 00:24:27.520 \longrightarrow 00:24:29.810$ then it would be useful to know
- $406\ 00:24:29.810 \longrightarrow 00:24:32.263$ where the actual ignition site,
- $407\ 00:24:33.460 \longrightarrow 00:24:35.483$ the site of ignition was.
- $408\ 00:24:37.020 \longrightarrow 00:24:41.090$ Where did the fire occur originally?
- $409\ 00:24:41.090 \longrightarrow 00:24:44.380$ And many of these fires are actually discovered
- 410 00:24:44.380 --> 00:24:47.610 out in the wild, far away from humans.
- $411\ 00:24:47.610 \longrightarrow 00:24:50.000$ And there's a lot of uncertainty.
- $412\ 00{:}24{:}50.000 \dashrightarrow 00{:}24{:}54.133$ There's actually a large swaths of land that are involved.
- 413 00:24:57.010 --> 00:25:00.030 Finally, this, this global influenza data
- $414\ 00:25:00.030 \longrightarrow 00:25:02.620$ is very nice for certain reasons.
- $415\ 00:25:02.620 \longrightarrow 00:25:06.730$ For example, it features all of the observations,
- 416 00:25:06.730 --> 00:25:09.720 actually provide a viral genome data.
- $417\ 00:25:09.720 \longrightarrow 00:25:12.370$ So we can perform other more complex
- $418\ 00:25:12.370 \longrightarrow 00:25:13.610$ analyses on the data.

- 419 00:25:13.610 --> 00:25:16.120 And in fact, I'll do that in the third section
- $420\ 00:25:17.360 \longrightarrow 00:25:18.563$ for related data.
- $421\ 00:25:20.849 \longrightarrow 00:25:24.900$ But the actual spatial precision for this data is very poor.
- 422 00:25:24.900 --> 00:25:28.550 So, for some of these viral cases,
- $423\ 00:25:28.550 \longrightarrow 00:25:31.890$ we know the city in which it occurred.
- $424\ 00:25:31.890 \longrightarrow 00:25:33.750$ For some of them, we know the region
- $425\ 00:25:33.750 \longrightarrow 00:25:35.200$ or the state in which it occurred.
- $426\ 00:25:35.200 \longrightarrow 00:25:37.100$ And for some of them, we know the country
- $427\ 00:25:37.100 \longrightarrow 00:25:38.150$ in which it occurred.
- $428\ 00:25:40.230 \longrightarrow 00:25:42.050$ So I'm gonna start with the easy problem,
- $429\ 00{:}25{:}42.050$ --> $00{:}25{:}47.050$ which is analyzing the DC gun violence, the DC gunshot data.
- $430\ 00{:}25{:}47.740 {\:\hbox{--}}{>}\ 00{:}25{:}50.440$ And here again, the police department rounds the data
- $431\ 00:25:50.440 \longrightarrow 00:25:52.150$ to the nearest hundred meters.
- $432\ 00:25:52.150 \longrightarrow 00:25:53.260$ So what do we do?
- $433\ 00:25:53.260 \longrightarrow 00:25:56.510$ We take that at face value and we simply use,
- $434\ 00:25:56.510 --> 00:26:00.950$ place a uniform prior over the 10,000 meters square
- $435\ 00{:}26{:}03.650 \dashrightarrow 00{:}26{:}06.260$ that is centered at each one of our observations.
- 436 00:26:06.260 --> 00:26:10.270 So here I'm denoting our actual data,
- 437 00:26:10.270 --> 00:26:14.500 our observed data with this kind of Gothic X,
- $438\ 00:26:14.500 \longrightarrow 00:26:16.930$ and then I'm placing a prior over the location
- $439\ 00:26:16.930 \longrightarrow 00:26:18.990$ at which the gunshot actually occurred.
- $440\ 00{:}26{:}18.990 \dashrightarrow 00{:}26{:}23.120$ And this is a uniform prior over a box centered at my data.
- $441\ 00{:}26{:}23.120$ --> $00{:}26{:}28.050$ And using this prior actually has another interpretation
- $442\ 00:26:28.050 \longrightarrow 00:26:32.740$ similar to some other concepts
- $443\ 00:26:32.740 \longrightarrow 00:26:35.770$ from the missing data literature.

- $444\ 00{:}26{:}35.770 \dashrightarrow 00{:}26{:}40.470$ And use of this prior actually corresponds to using
- 445 00:26:40.470 --> 00:26:43.010 something called the group data likelihood.
- $446~00{:}26{:}43.010 \dashrightarrow 00{:}26{:}48.010$ And it's akin to the expected, complete data likelihood
- $447\ 00{:}26{:}48.429 \dashrightarrow 00{:}26{:}52.543$ if you're familiar with the missing data literature
- $448\ 00{:}26{:}53.460 \dashrightarrow 00{:}26{:}56.980$ So what we do, and I'm not gonna get too much into
- 449 00:26:56.980 --> 00:27:00.130 the inference at this point, but we actually use MCMC
- 450 00:27:00.130 --> 00:27:03.890 to simultaneously infer the locations,
- $451\ 00:27:03.890 \longrightarrow 00:27:07.680$ and the Hawkes model parameters,
- $452\ 00:27:07.680 \longrightarrow 00:27:10.203$ the rate function parameters at the same time.
- $453\ 00{:}27{:}12.310 \dashrightarrow 00{:}27{:}14.690$ So here, I'm just showing you a couple of examples
- $454\ 00:27:14.690 \longrightarrow 00:27:16.470$ of what this looks like.
- $455\ 00{:}27{:}16.470 \dashrightarrow 00{:}27{:}19.620$ For each one of our observations colored yellow,
- $456\ 00:27:19.620 \longrightarrow 00:27:22.283$ we then have 100 posterior samples.
- $457\ 00:27:24.540 --> 00:27:28.110$ So these dynamics can take on different forms
- $458\ 00{:}27{:}28.110 \dashrightarrow 00{:}27{:}32.000$ and they take on different forms in very complex ways,
- $459\ 00:27:32.000$ --> 00:27:36.340 simply because what we're essentially doing when we're...
- $460\ 00:27:38.190 \longrightarrow 00:27:40.950$ I'm going to loosely use the word impute.
- $461\ 00{:}27{:}40.950 \dashrightarrow 00{:}27{:}44.180$ When we're imputing this data, when we're actually inferring
- 462 00:27:44.180 --> 00:27:47.370 these locations, we're basically simulating
- $463\ 00:27:47.370 \longrightarrow 00:27:50.653$ from a very complex n-body problem.
- 464 00:27:52.920 --> 00:27:57.120 So on the left, how can we interpret this?
- $465\ 00{:}27{:}57.120 \dashrightarrow 00{:}28{:}00.760$ Well, we've got these four points and the model believes
- 466 00:28:00.760 --> 00:28:02.430 that actually they are farther away

- $467\ 00:28:02.430 \longrightarrow 00:28:03.990$ from each other than observed.
- $468\ 00:28:03.990 \longrightarrow 00:28:05.110$ Why is that?
- $469\ 00:28:05.110 \longrightarrow 00:28:08.960$ Well, right in the middle here, we have a shopping center,
- $470\ 00:28:08.960 \longrightarrow 00:28:12.980$ where there's actually many less gunshots.
- 471 00:28:12.980 --> 00:28:14.750 And then we've got residential areas
- $472\ 00{:}28{:}14.750 \dashrightarrow 00{:}28{:}18.070$ where there are many more gunshots on the outside.
- $473\ 00:28:18.070 \longrightarrow 00:28:21.513$ And the bottom right, we actually have all of these,
- $474\ 00{:}28{:}25.550 \dashrightarrow 00{:}28{:}30.090$ we believe that the actual locations of these gunshots
- $475\ 00{:}28{:}30.090 \dashrightarrow 00{:}28{:}34.180$ collect closer together, kind of toward a very high
- 476 00:28:34.180 --> 00:28:36.883 intensity region in Washington, DC.
- $477\ 00:28:39.400 \longrightarrow 00:28:40.930$ And then we can just think about
- $478\ 00:28:40.930 \longrightarrow 00:28:43.910$ the general posterior displacement.
- $479\ 00:28:43.910 \longrightarrow 00:28:45.670$ So the mean posterior displacement.
- 480 00:28:45.670 --> 00:28:48.443 So in general, are there certain points that,
- $481\ 00{:}28{:}49.941 \longrightarrow 00{:}28{:}53.420$ where the model believes that the gunshots occurred
- 482 00:28:53.420 --> 00:28:57.510 further away from the observed events?
- $483\ 00:28:57.510 \longrightarrow 00:28:59.923$ And in general, there's not really.
- 484 00:29:01.380 --> 00:29:04.190 It's hard to come up with any steadfast rules.
- $485\ 00{:}29{:}04.190 \dashrightarrow 00{:}29{:}07.860$ For example, in the bottom, right, we have some shots,
- $486\ 00:29:07.860 --> 00:29:12.700$ some gunshots that show a very large posterior displacement,
- 487 00:29:12.700 --> 00:29:15.380 and they're in a very high density region.
- $488\ 00:29:15.380 --> 00:29:18.590$ Whereas on the top, we also get large displacement
- $489\ 00{:}29{:}18.590 \dashrightarrow 00{:}29{:}21.210$ and we're not surrounded by very many gunshots at all.
- $490\ 00:29:21.210 --> 00:29:24.250$ So it is a very complex n-body problem

- $491\ 00:29:24.250 \longrightarrow 00:29:25.803$ that we're solving.
- 492 00:29:27.330 --> 00:29:29.500 And the good news is, for this problem,
- 493 00:29:29.500 --> 00:29:31.750 it doesn't matter much anyway.
- $494\ 00{:}29{:}31.750 \dashrightarrow 00{:}29{:}34.563$ The results that we get are pretty much the same.
- $495\ 00:29:37.410 \longrightarrow 00:29:42.250\ I$ mean, so from the standpoint of statistical significance,
- $496\ 00:29:42.250 \longrightarrow 00:29:44.920$ we do get some statistically significant results.
- $497\ 00:29:44.920 \longrightarrow 00:29:47.390$ So in this figure, on the top,
- 498 00:29:47.390 --> 00:29:50.560 I'm showing you 95% credible intervals,
- $499\ 00{:}29{:}50.560$ --> $00{:}29{:}55.560$ and this is the self excitatory spatial length scale.
- 500 00:29:55.560 --> 00:29:57.040 We believe that it's smaller,
- 501~00:29:57.040 --> 00:30:00.550 but from a practical standpoint, it's not much smaller.
- 502 00:30:00.550 --> 00:30:02.840 It's a difference between 60 meters
- 503 00:30:02.840 --> 00:30:06.823 and maybe it's at 73 meters, 72 meters.
- $504~00:30:12.500 \longrightarrow 00:30:15.550$ But we shouldn't take too much comfort
- $505\ 00{:}30{:}15.550 \dashrightarrow 00{:}30{:}18.910$ because actually as we increase the spatial prec-
- $506\ 00:30:18.910 --> 00:30:21.840$ excuse me, as we decrease the spatial precision,
- $507~00{:}30{:}21.840 \dashrightarrow 00{:}30{:}25.210$ we find that the model that does not take account
- 508 00:30:26.120 --> 00:30:28.780 of the rounding, performs much worse.
- 509 00:30:28.780 --> 00:30:32.760 So for example, if you look in the table,
- $510\ 00:30:32.760 \longrightarrow 00:30:36.373$ then we have the fixed locations model,
- $511\ 00:30:37.310 \longrightarrow 00:30:40.050$ where I'm not actually inferring the locations.
- $512~00{:}30{:}40.050 \dashrightarrow 00{:}30{:}44.590$ And I just want to see, what's the empirical coverage
- $513\ 00:30:44.590 \longrightarrow 00:30:47.003$ of the 95% credible intervals?
- $514\ 00:30:48.010 \longrightarrow 00:30:52.580$ And let's just focus on the 95%
- 515 00:30:52.580 --> 00:30:54.900 credible intervals, specifically,
- $516\ 00:30:54.900 \longrightarrow 00:30:58.670$ simply because actually the other intervals,

- 517~00:30:58.670 --> 00:31:03.230 the 50% credible interval, the 80% credible interval,
- $518\ 00:31:03.230 \longrightarrow 00:31:07.263$ they showed the similar dynamic, which is that as we,
- 519 00:31:09.520 --> 00:31:12.500 so if we start on the right-hand side,
- $520\ 00:31:12.500 \longrightarrow 00:31:16.260$ we have precision down to down to 0.1.
- $521\ 00:31:16.260 \longrightarrow 00:31:19.370$ This is a unit list example.
- 522 00:31:19.370 --> 00:31:21.940 So we have higher precision, actually.
- 523 00:31:21.940 --> 00:31:24.160 Then we see that we have very good coverage,
- $524\ 00:31:24.160 --> 00:31:27.957$ even if we don't take this locational
- $525\ 00:31:30.550 \longrightarrow 00:31:32.303$ coarsening into account.
- $526\ 00:31:33.160 --> 00:31:38.020$ But as we increase the size of our error box,
- $527\ 00:31:38.020 \longrightarrow 00:31:40.960$ then we actually lose coverage,
- $528\ 00:31:40.960 --> 00:31:43.720$ and we deviate from that 95% coverage.
- 529 00:31:43.720 --> 00:31:46.290 And then finally, if we increase too much,
- 530 00:31:46.290 --> 00:31:48.770 then we're never actually going to be
- 531 00:31:50.800 --> 00:31:55.563 capturing the true spatial length scale,
- $532\ 00:31:56.740 \longrightarrow 00:31:59.040$ whereas if we actually do sample the locations,
- 533 00:31:59.040 --> 00:32:00.970 we perform surprisingly well,
- $534\ 00:32:00.970 \dashrightarrow 00:32:05.893$ even when we have a very high amount of spatial coarsening.
- $535\ 00:32:08.010 \longrightarrow 00:32:10.550$ Well, how else can we break the model?
- 536 00:32:10.550 --> 00:32:12.750 Another way that we can break this model,
- $537~00{:}32{:}12.750 \dashrightarrow 00{:}32{:}15.690$ and by break the model, I mean, my naive model
- $538~00{:}32{:}15.690 \dashrightarrow 00{:}32{:}18.320$ where I'm not inferring the locations.
- $539\ 00:32:18.320 \longrightarrow 00:32:21.710$ Another way that we can break this model
- 540 00:32:21.710 --> 00:32:24.380 is simply by considering data
- 541 00:32:24.380 --> 00:32:28.400 where we have variable spatial coarsening.
- 542 00:32:28.400 --> 00:32:30.860 That is where different data points
- 543 00:32:31.710 --> 00:32:34.270 are coarsened different amounts,
- $544\ 00:32:34.270 \longrightarrow 00:32:36.683$ so we have a variable precision.

- 545 00:32:40.290 --> 00:32:42.850 So considering the wildfire data,
- $546\ 00:32:42.850 \longrightarrow 00:32:47.850$ we actually see something with the naive approach
- $547\ 00:32:48.480 \longrightarrow 00:32:51.010$ where we're not inferring the locations.
- 548~00:32:51.010 --> 00:32:55.960 We actually see something that is actually recorded
- $549\ 00:32:55.960 \longrightarrow 00:33:00.370$ elsewhere in the Hawkes process literature.
- $550\ 00:33:00.370 \longrightarrow 00:33:04.560$ And that is that when we try to use a flexible
- 551 00:33:04.560 --> 00:33:07.360 background function, as we are trying to do,
- $552\ 00{:}33{:}07.360 \dashrightarrow 00{:}33{:}11.933$ then we get this multimodal posterior distribution.
- 553 00:33:12.780 --> 00:33:14.350 And that's fine.
- 554 00:33:14.350 --> 00:33:17.410 We can also talk about it in a frequentist,
- 555 00:33:17.410 --> 00:33:18.710 from the frequency standpoint,
- $556\ 00:33:18.710 \longrightarrow 00:33:21.360$ because it's observed there as well
- 557 00:33:21.360 --> 00:33:24.910 in the maximum likelihood context, which is,
- $558\ 00:33:24.910 \longrightarrow 00:33:27.560$ we still see this multimodality.
- $559\ 00:33:28.740 --> 00:33:32.253$ What specific form does this multimodality take?
- $560~00:33:33.710 \longrightarrow 00:33:38.710$ So what we see is that we get modes around the places
- $561~00{:}33{:}39.970 \dashrightarrow 00{:}33{:}44.970$ where the background rate parameters,
- $562~00{:}33{:}46.750 {\:{\mbox{--}}\!>} 00{:}33{:}49.600$ the background length scale parameters are equal
- $563\ 00:33:49.600 -> 00:33:52.950$ to the temporal, excuse me, the self excitatory
- $564\ 00:33:54.040 --> 00:33:55.830$ length scale parameters.
- $565\ 00:33:55.830 \longrightarrow 00:33:59.190$ So for the naive model, it's mode A,
- $566\ 00:34:00.280 \longrightarrow 00:34:02.560$ it believes that the spatial length scale
- $567~00{:}34{:}02.560 \dashrightarrow 00{:}34{:}07.410$ is about 24 kilometers, and that the spatial length scale
- $568\ 00:34:07.410 --> 00:34:09.160$ of the self excitatory dynamics
- $569\ 00:34:09.160 \longrightarrow 00:34:13.930$ are also roughly 24 kilometers.
- 570 00:34:13.930 --> 00:34:15.330 And then for the other mode,

- $571\ 00:34:16.180 --> 00:34:19.970$ we get equal temporal length scales.
- $572\ 00:34:19.970 \longrightarrow 00:34:23.930$ So here, it believes 10 days, and 10 days
- $573\ 00:34:23.930 \longrightarrow 00:34:27.320$ for the self excitatory in the background component.
- $574\ 00:34:27.320 \longrightarrow 00:34:29.010$ And this can be very bad indeed.
- 575 00:34:29.010 --> 00:34:31.430 So for example, for mode A,
- $576\ 00:34:31.430 --> 00:34:35.910$ it completely, the Hawkes model completely fails
- $577\ 00{:}34{:}35.910 \dashrightarrow 00{:}34{:}40.400$ to capture seasonal dynamics, which is the first thing
- 578 00:34:40.400 --> 00:34:42.910 that you would want it to pick up on.
- $579\ 00{:}34{:}42{:}910 \dashrightarrow 00{:}34{:}46{.}690$ The first thing that you would want it to understand
- $580\ 00:34:46.690 \longrightarrow 00:34:49.060$ is that wildfires...
- $581\ 00:34:49.060 --> 00:34:50.650$ Okay, I need to be careful here
- $582\ 00:34:50.650 --> 00:34:52.643$ because I'm not an expert on wildfires.
- 583 00:34:54.610 --> 00:34:55.830 I'll go out on a limb and say,
- 584~00:34:55.830 --> 00:34:59.983 wildfires don't happen in Alaska during the winter.
- $585\ 00:35:02.920 \longrightarrow 00:35:05.060$ On the other hand, when we use the full model
- $586\ 00{:}35{:}05.060 \dashrightarrow 00{:}35{:}08.450$ and we're actually simultaneously inferring the locations,
- $587\ 00:35:08.450 --> 00:35:10.950$ then we get this kind of Goldilocks effect,
- 588 00:35:10.950 --> 00:35:14.400 where here, the spatial length scale
- 589 00:35:14.400 --> 00:35:17.010 is somewhere around 35 kilometers,
- $590~00{:}35{:}17.010 \dashrightarrow 00{:}35{:}20.840$ which is between the 23 kilometers and 63 kilometers
- $591\ 00:35:20.840 --> 00:35:25.840$ for mode modes A and B, and we see that reliably.
- 592~00:35:33.160 --> $00:35:36.843~\mathrm{I}$ can stop for some questions because I'm making good time.
- 593 00:35:44.025 --> 00:35:49.025 <v Man>Does any body have any questions, if you want to ask?</v>
- $594\ 00:35:52.120 --> 00:35:53.430 < v\ Student>What's the interpretation < /v>$

- $595\ 00:35:53.430 \longrightarrow 00:35:56.180$ of the spatial length scale and the temporal length scale?
- $596\ 00:35:56.180 \longrightarrow 00:35:58.910$ What do those numbers actually mean?
- 597 00:35:58.910 --> 00:36:02.180 <v -> Yeah, thank you.</v>
- 598 00:36:02.180 --> 00:36:06.230 So, the interpretation of the...
- $599\ 00:36:06.230 \longrightarrow 00:36:10.660$ I think that the most useful interpretation,
- $600\ 00{:}36{:}10.660 \dashrightarrow 00{:}36{:}14.910$ so just to give you an idea of how they can be interpreted.
- $601~00{:}36{:}14.910 \dashrightarrow 00{:}36{:}19.770$ So for example, for the self excitatory component, right,
- $602~00{:}36{:}19.770 \dashrightarrow 00{:}36{:}22.283$ that's describing the contagion dynamics.
- $603\ 00:36:23.420 \longrightarrow 00:36:28.420$ What this is saying is that if we see a wildfire,
- $604\ 00:36:29.110 \longrightarrow 00:36:32.400$ then we expect to observe another wildfire
- $605\ 00:36:34.020 \longrightarrow 00:36:38.193$ with mean distribution of one day.
- $606\ 00:36:40.750 \longrightarrow 00:36:45.750$ So the temporal length scale is in units days.
- $607\ 00{:}36{:}46.120 \dashrightarrow 00{:}36{:}49.740$ So in the full model, after observing the wild-fire,
- $608~00{:}36{:}49.740 \dashrightarrow 00{:}36{:}53.520$ we expect to see another wild fire with mean, you know,
- $609\ 00:36:53.520 \longrightarrow 00:36:55.143$ on average, the next day.
- $610\ 00{:}36{:}56{.}390 {\: \hbox{--}}{>}\ 00{:}37{:}01{.}390$ And this of course, you know, we have this model
- $611\ 00:37:01.620 \longrightarrow 00:37:05.250$ that's taking space and time into account.
- $612\ 00{:}37{:}05.250 {\: -->\:} 00{:}37{:}10.020$ So the idea though, is that because of the separability
- 613 00:37:10.020 --> 00:37:12.200 in our model, we're basically simply
- $614\ 00:37:12.200 \longrightarrow 00:37:14.343$ expecting to see it somewhere.
- 615 00:37:18.920 --> 00:37:19.987 <v Student>Thank you.</v>
- 616 00:37:23.960 --> 00:37:25.960 <- Man>Any other questions?</v>
- 617 00:37:25.960 --> 00:37:29.627 (man speaking indistinctly)
- 618 00:37:30.620 --> 00:37:32.620 <v Student>Hi, can I have one question?</v>
- $619\ 00:37:34.520 \longrightarrow 00:37:35.890 < v \longrightarrow Go \ head. < /v >$

- $620\ 00:37:35.890 \longrightarrow 00:37:37.573 < v\ Student>Okay.</v>$
- $621\ 00:37:37.573 \longrightarrow 00:37:38.406\ I'm\ curious.$
- $622\ 00:37:38.406 \longrightarrow 00:37:39.277$ What is a main difference between
- $623\ 00:37:39.277 --> 00:37:42.850$ the naive model A and the naive model B?
- $624\ 00:37:42.850 \longrightarrow 00:37:43.683 < v \longrightarrow Okay. < /v >$
- 625 00:37:43.683 --> 00:37:44.761 So, sorry.
- $626\ 00:37:44.761 \longrightarrow 00:37:45.594$ This is...
- 627 00:37:46.860 --> 00:37:49.260 I think I could have presented
- $628\ 00:37:49.260 \longrightarrow 00:37:52.070$ this aspect better within the table itself.
- $629\ 00:37:52.070 \longrightarrow 00:37:55.263$ So this is the same exact model.
- 630 00:37:57.680 --> 00:38:00.520 But all that I'm doing is I'm applying
- $631\ 00:38:00.520 \longrightarrow 00:38:02.840$ the model multiple times.
- 632~00:38:02.840 --> 00:38:05.893 So in this case, I'm using Markov chain Monte Carlo.
- 633 00:38:07.490 --> 00:38:09.850 So one question that you might ask is,
- $634~00{:}38{:}09.850 \dashrightarrow 00{:}38{:}14.850$ well, what happens when I run MCMC multiple times?
- 635 00:38:16.490 --> 00:38:20.060 Sometimes I get trapped in one mode.
- $636\ 00:38:20.060 \longrightarrow 00:38:22.370$ Sometimes I get trapped in another mode.
- 637 00:38:22.370 --> 00:38:25.050 You can just for, you know, a mental cartoon,
- 638 00:38:25.050 --> 00:38:27.090 we can think of like a (indistinct)
- $639\ 00:38:27.090 \longrightarrow 00:38:29.680$ a mixture of Gaussian distribution, right.
- 640~00:38:29.680 --> 00:38:33.720 Sometimes I can get trapped in this Gaussian component.
- $641\ 00:38:33.720$ --> 00:38:36.570 Sometimes I could get trapped in this Gaussian component.
- $642\ 00{:}38{:}38.290 \to 00{:}38{:}43.290$ So there's nothing intrinsically wrong with multimodality.
- $643\ 00:38:43.760 \longrightarrow 00:38:47.490$ We prefer to avoid it as best we can simply because it makes
- $644\ 00:38:47.490 --> 00:38:49.963$ interpretation much more difficult.
- 645 00:38:52.040 --> 00:38:56.010 In this case, if I only perform inference

- $646~00{:}38{:}56.010 \dashrightarrow 00{:}38{:}59.560$ and only see mode A, then I'm never actually gonna be
- $647\ 00:38:59.560 \longrightarrow 00:39:04.560$ picking up on seasonal dynamics.
- $648\ 00:39:07.320 \longrightarrow 00:39:08.470$ Does that (indistinct)?
- $649\ 00:39:09.760 --> 00:39:11.900 < v\ Woman> Yeah, it's clear. </v>$
- $650\ 00:39:11.900 --> 00:39:13.080 < v \ Instructor>Okay.</v>$
- 651 00:39:13.080 --> 00:39:15.510 <v Woman>Okay, and I also (indistinct).</v>
- $652\ 00:39:15.510 \longrightarrow 00:39:18.030$ So for the full model, you can capture
- $653\ 00:39:18.030 \longrightarrow 00:39:20.820$ the spatial dynamic property.
- $654\ 00:39:20.820 \longrightarrow 00:39:22.740$ So how to do that?
- $655~00{:}39{:}22.740 \dashrightarrow 00{:}39{:}25.437$ So I know you need the Hawkes process that sees,
- $656\ 00:39:25.437 \longrightarrow 00:39:28.150$ clarifies the baseline.
- 657 00:39:28.150 --> 00:39:31.600 So how do you estimate a baseline part?
- $658\ 00:39:31.600 \longrightarrow 00:39:32.777 < v \longrightarrow Oh$, okay, great.</v>
- $659\ 00:39:34.574 \longrightarrow 00:39:35.743$ In the exact same way.
- 660 00:39:37.280 --> 00:39:39.130 <v Student>Okay, I see.</v>
- 661 00:39:39.130 --> 00:39:44.130 <v -> So I'm jointly, simultaneously performing inference </v>
- $662\ 00:39:44.610 \longrightarrow 00:39:47.380$ over all of the model parameters.
- $663\ 00:39:47.380 --> 00:39:50.993$ And I can go all the way back.
- $664\ 00:39:53.320 \longrightarrow 00:39:54.419$ Right.
- 665 00:39:54.419 --> 00:39:56.519 'Cause it's actually a very similar model.
- 666 00:39:57.960 --> 00:39:58.793 Yes.
- $667\ 00:39:58.793 \longrightarrow 00:40:01.560$ So this is my baseline.
- $668\ 00{:}40{:}01.560 \dashrightarrow 00{:}40{:}05.720$ And so, for example, when we're talking about that temporal
- 669 00:40:05.720 --> 00:40:09.050 smooth that you saw on that last figure,
- $670~00{:}40{:}09.050 \dashrightarrow 00{:}40{:}13.390$ where I'm supposed to be capturing seasonal dynamics.
- 671 00:40:13.390 --> 00:40:17.790 Well, if tau T, which I'm just calling
- $672\ 00:40:17.790 \longrightarrow 00:40:21.728$ my temporal length scale, if that is too large,

- 673 00:40:21.728 --> 00:40:24.310 then I'm never going to be capturing
- $674\ 00{:}40{:}24.310 \dashrightarrow 00{:}40{:}28.430$ those seasonal dynamics, which I would be hoping to capture
- 675 00:40:28.430 --> 00:40:30.943 precisely using this background smoother.
- $676\ 00:40:33.080 \longrightarrow 00:40:34.040 < v \ Student>Okay, \ I \ see.</v>$
- $677\ 00:40:34.040 \longrightarrow 00:40:37.850$ So it looks like they assume the formula for the baseline,
- $678\ 00:40:37.850$ --> 00:40:41.910 and then you estimates some parameters in these formulas.
- 679 00:40:41.910 --> 00:40:43.210 <v ->Yes.</v>
- 680 00:40:43.210 --> 00:40:44.190 <v Student>In my understanding,</v>
- 681 00:40:44.190 --> 00:40:47.060 in the current Hawkes literature,
- 682 00:40:47.060 --> 00:40:48.680 somebody uses (indistinct) function
- $683\ 00:40:48.680 \longrightarrow 00:40:51.500$ to approximate baseline also.
- $684\ 00:40:51.500 \longrightarrow 00:40:52.333 < v \longrightarrow Yes. < /v >$
- $685\ 00:40:52.333 \longrightarrow 00:40:53.906 < v \ Student> This is also interesting. </v>$
- 686 00:40:53.906 --> 00:40:54.895 Thank you. <v ->Yes.</v>
- 687 00:40:54.895 --> 00:40:55.728 Okay, okay, great.
- 688 00:40:55.728 --> 00:40:59.080 I'm happy to show another, you know.
- 689 00:40:59.080 --> 00:41:00.380 And of course I did not invent this.
- $690\ 00:41:00.380 \longrightarrow 00:41:03.030$ This is just another tact that you can take.
- $691\ 00:41:03.030 --> 00:41:03.880 < v \ Student> Yeah, yeah, yeah, yeah. < /v>$
- 692 00:41:03.880 --> 00:41:04.713 That's interesting.
- $693\ 00:41:04.713 \longrightarrow 00:41:05.546$ Thanks
- 694 00:41:05.546 --> 00:41:06.379 <v -> Yup. </v>
- $695\ 00:41:09.810 \longrightarrow 00:41:11.810 < v \ Student > As just a quick follow up on < / v > 10:41:10 < v \ Student > As just a quick follow up on < / v > 10:41:10 < v \ Student > 10:41:10 < v \ Studen$
- 696 00:41:12.860 --> 00:41:16.140 when you were showing the naive model,
- $697\ 00:41:16.140 --> 00:41:18.513$ and this maybe a naive question on my part.
- $698\ 00:41:19.920 --> 00:41:23.980$ Did you choose naive model A to be the one
- $699~00{:}41{:}23.980 \dashrightarrow 00{:}41{:}26.680$ that does the type seasonality or is that approach
- 700 00:41:26.680 --> 00:41:31.013 just not (indistinct) seasonality?

```
701 00:41:32.950 --> 00:41:36.780 <v ->So I think that the point</v>
```

702 00:41:38.030 --> 00:41:41.650 is that sometimes based on, you know,

703 00:41:41.650 --> 00:41:43.550 I'm doing MCMC.

704 00:41:43.550 --> 00:41:46.320 It's random in nature, right.

 $705\ 00:41:46.320 \longrightarrow 00:41:49.070$ So just sometimes when I do that,

706 00:41:49.070 --> 00:41:52.550 I get trapped in that mode A,

 $707\ 00:41:52.550 --> 00:41:54.943$ and sometimes I get trapped in that mode B.

708 00:41:59.560 --> 00:42:03.660 The label that I apply to it is just arbitrary,

709 00:42:03.660 --> 00:42:06.113 but maybe I'm not getting your question.

710 00:42:10.880 --> 00:42:13.830 <v Student>No, I think you did.</v>

 $711\ 00:42:13.830 \longrightarrow 00:42:16.820$ So, it's possible that we detect it.

 $712\ 00:42:16.820 \longrightarrow 00:42:18.430$ It's possible that we don't.

713 00:42:20.045 --> 00:42:20.878 <-> Exactly.</v>

714 00:42:20.878 --> 00:42:22.000 And that's, you know,

715 00:42:22.000 --> 00:42:23.263 <v Student>That's what it is.</v>

716 00:42:23.263 --> 00:42:24.760 <v ->multimodality.</v>

717 00:42:24.760 --> 00:42:26.830 So this is kind of nice though,

718 00:42:26.830 --> 00:42:29.970 that this can actually give you,

719 00:42:29.970 --> 00:42:32.973 that actually inferring the locations can somehow,

 $720\ 00:42:34.560 \longrightarrow 00:42:37.330$ at least in this case, right,

721 00:42:37.330 --> 00:42:40.000 I mean, this is a case study, really,

 $722\ 00:42:40.000 \longrightarrow 00:42:43.260$ that this can help resolve that multimodality.

723 00:42:46.640 --> 00:42:48.315 <v Student>Thank you.</v>

 $724\ 00:42:48.315 \longrightarrow 00:42:49.148$ Yeah.

725 00:42:49.148 --> 00:42:54.148 <
v Student>So back to the comparison between CPU and GPU.
</v>

726 00:42:54.820 --> 00:42:59.700 Let's say, if we increase the thread of CPU,

 $727\ 00{:}42{:}59.700 \dashrightarrow 00{:}43{:}04.700$ say like to infinity, will it be possible that the speed

 $728\ 00:43:05.737 \longrightarrow 00:43:09.033$ of CPU match the speed up of GPU?

729 00:43:11.810 --> 00:43:12.643 <v ->So.</v>

- $730\ 00:43:15.170 \longrightarrow 00:43:16.760$ You're saying if we increase.
- 731 00:43:16.760 --> 00:43:18.590 So, can I ask you one more time?
- 732 00:43:18.590 --> 00:43:21.190 Can I just ask for clarification?
- 733 00:43:21.190 --> 00:43:23.733 You're saying if we increase what to infinity?
- $734\ 00:43:24.640 --> 00:43:26.187 < v \ Student> The thread of CPU.</v>$
- $735~00{:}43{:}27.560 \dashrightarrow 00{:}43{:}31.520~\mathrm{I}$ think in the graph you're increasing the threads
- $736\ 00:43:31.520 \longrightarrow 00:43:34.203$ of CPU from like one to 80.
- $737\ 00:43:35.380 \longrightarrow 00:43:39.030$ And the speed up increase as the number
- 738 00:43:39.030 --> 00:43:41.770 of threats increasing.
- 739 00:43:41.770 --> 00:43:44.860 So just say like, let's say the threads of CPU
- 740 00:43:44.860 --> 00:43:49.860 increase to infinity, will the speed up match,
- 741 00:43:50.540 --> 00:43:53.690 because GPU with like (indistinct).
- 742 00:43:53.690 --> 00:43:55.843 Very high, right. < v -> Yeah, yeah. < / v >
- 743 00:43:57.080 --> 00:43:59.510 Let me show you another figure,
- $744\ 00:43:59.510 \longrightarrow 00:44:01.603$ and then we can return to that.
- 745 00:44:02.747 --> 00:44:05.363 I think it's a good segue into the next section.
- $746\ 00:44:06.960 \longrightarrow 00:44:09.060$ So, let me answer that in a couple slides.
- 747 00:44:10.171 --> 00:44:11.740 <v Student>Okay, sounds good.</v>
- 748 00:44:11.740 --> 00:44:12.573 <v ->Okay.</v>
- $749\ 00:44:12.573 \longrightarrow 00:44:15.180$ So, questions about.
- 750 00:44:15.180 --> 00:44:17.630 I've gotten some good questions about how do we interpret
- $751\ 00:44:17.630 \longrightarrow 00:44:22.630$ the length scales and then this makes me think about,
- 752 00:44:23.380 --> 00:44:25.970 well, if all that we're doing is interpreting
- $753\ 00{:}44{:}25.970 \dashrightarrow 00{:}44{:}29.200$ the length scales, how much is that telling us about
- 754 00:44:29.200 --> 00:44:32.130 the phenomenon that we're interested in?
- $755\ 00{:}44{:}32.130 \dashrightarrow 00{:}44{:}36.540$ And can we actually craft more complex hierarchical models
- $756~00{:}44{:}36.540 \dashrightarrow 00{:}44{:}40.500$ so that we can actually learn something perhaps

- $757\ 00:44:40.500 --> 00:44:42.750$ even biologically interpretable?
- 758 00:44:42.750 --> 00:44:46.650 So here, I'm looking at 2014, 2016
- 759 00:44:46.650 --> 00:44:49.650 Ebola virus outbreak data.
- 760 $00:44:49.650 \longrightarrow 00:44:53.870$ This is over almost 22,000 cases.
- $761\ 00:44:53.870 \longrightarrow 00:44:58.697$ And of these cases, we have about 1600
- $762\ 00:45:00.320 \longrightarrow 00:45:04.993$ that are providing us genome data.
- $763\ 00:45:07.630 --> 00:45:12.110$ And then of those 1600, we have a smaller subset
- $764\ 00:45:12.110$ --> 00:45:17.110 that provide us genome data, as well as spatiotemporal data.
- $765~00{:}45{:}19.630 \dashrightarrow 00{:}45{:}24.630$ So often people use genome data, say RNA sequences in order
- 766 00:45:26.640 --> 00:45:29.100 to try to infer the way that different viral cases
- $767\ 00:45:29.100 \longrightarrow 00:45:31.140$ are related to each other.
- $768~00{:}45{:}31.140 \dashrightarrow 00{:}45{:}34.030$ And the question is, can we pull together sequenced
- 769 00:45:34.030 --> 00:45:36.233 and unsequenced data at the same time?
- 770 00:45:38.990 --> 00:45:42.170 So what I'm doing here is, again,
- 771 00:45:42.170 --> 00:45:44.090 I'm not inventing this.
- $772\ 00:45:44.090 --> 00:45:46.870$ This is something that already exists.
- 773 00:45:46.870 --> 00:45:51.870 So all that I'm doing is modifying my triggering function G,
- $774\ 00:45:52.160 \longrightarrow 00:45:53.670$ and giving it this little N,
- 775 00:45:53.670 --> 00:45:57.310 this little subscript right there,
- 776 00:45:57.310 --> 00:46:01.480 which is denoting the fact that I'm allowing different viral
- $777\ 00:46:01.480 \longrightarrow 00:46:04.660$ observations to contribute to the rate function
- $778\ 00:46:04.660 \longrightarrow 00:46:05.993$ in different manners.
- 779 00:46:07.180 --> 00:46:09.240 And the exact form that that's gonna take on
- 780 00:46:09.240 --> 00:46:12.350 for my specific simple model that I'm using,
- 781 00:46:12.350 --> 00:46:16.560 is I'm going to give this this data N.
- $782\ 00:46:16.560 --> 00:46:19.890$ And I'm gonna include this data N parameter

783 00:46:19.890 --> 00:46:22.350 in my self excitatory component.

784 00:46:22.350 --> 00:46:26.563 And this data N is restricted to be greater than zero.

 $785\ 00:46:27.680 \longrightarrow 00:46:30.380$ So if it is greater than one,

 $786~00{:}46{:}30.380 \dashrightarrow 00{:}46{:}33.690$ I'm gonna assume that actually, this self excite,

787 00:46:33.690 --> 00:46:37.350 excuse me, that this particular observation,

 $788\ 00:46:37.350 --> 00:46:40.820$ little N is somehow more contagious.

 $789\ 00:46:40.820 \longrightarrow 00:46:42.660$ And if data is less than one,

 $790~00{:}46{:}42.660 \dashrightarrow 00{:}46{:}45.333$ then I'm going to assume that it's less contagious.

791 00:46:47.870 --> 00:46:51.610 And this is an entirely unsatisfactory part of my talk,

 $792~00{:}46{:}51.610 \dashrightarrow 00{:}46{:}56.610$ where I'm gonna gloss over a massive part of my model.

793 00:46:57.930 --> 00:47:00.570 And all that I'm gonna say is that

 $794~00:47:02.030 \longrightarrow 00:47:05.360$ this Phylogenetic Hawkes process, which I'm gonna be telling

 $795~00:47:05.360 \dashrightarrow 00:47:08.423$ you about in the context of big modeling,

 $796\ 00:47:09.270 \longrightarrow 00:47:13.040$ and that challenge is that we start

 $797\ 00:47:13.040 \longrightarrow 00:47:16.170$ with the phylogenetic tree, which is simply the family tree

 $798\ 00:47:16.170 \longrightarrow 00:47:21.170$ that is uniting my 1600 sequenced cases.

 $799\ 00:47:21.520 \longrightarrow 00:47:25.220$ And then based on that, actually conditioned on that tree,

800~00:47:25.220 --> 00:47:28.350 we're gonna allow that tree to inform the larger

 $801\ 00{:}47{:}28.350 \dashrightarrow 00{:}47{:}33.350$ co-variants of my model parameters, which are then going to

 $802\ 00:47:33.390 \longrightarrow 00:47:36.870$ contribute to the overall Hawkes rate function

 $803\ 00:47:36.870 --> 00:47:40.043$ in a differential manner, although it's still additive.

804 00:47:44.670 --> 00:47:48.560 Now, let's see.

805 00:47:48.560 --> 00:47:51.633 Do I get to go till 10 or 9:50?

- 806 00:47:56.560 --> 00:47:58.540 <v Man>So you can go till 10.</v>
- $807\ 00:47:58.540 \longrightarrow 00:47:59.770 < v \longrightarrow Okay, great. < /v >$
- 808 00:47:59.770 --> 00:48:04.770 So then, I'll quickly say that if I'm inferring
- $809\ 00:48:05.680 --> 00:48:10.197$ all of these rates, then I'm inferring over 1300 rates.
- $810\ 00:48:12.670 \longrightarrow 00:48:15.270$ So that is actually the dimensionality
- 811 00:48:15.270 --> 00:48:17.583 of my posterior distribution.
- 812 00:48:21.270 --> 00:48:23.140 So a tool that I can use,
- 813 00:48:23.140 --> 00:48:26.150 a classic tool over 50 years old at this point,
- $814\ 00{:}48{:}26.150 --> 00{:}48{:}29.290$ that I can use, is I can use the random walk metropolis
- 815 00:48:29.290 --> 00:48:32.420 algorithm, which is actually going to sample
- $816\ 00:48:32.420 \longrightarrow 00:48:35.830$ from the posterior distribution of these rates.
- $817~00{:}48{:}35.830 \longrightarrow 00{:}48{:}40.040$ And it's gonna do so in a manner that is effective
- $818\ 00{:}48{:}40.040$ --> $00{:}48{:}45.040$ in low dimensions, but not effective in high dimensions.
- $819\ 00:48:45.950 \longrightarrow 00:48:47.390$ And the way that it works is say,
- $820\ 00:48:47.390 \longrightarrow 00:48:49.230$ we start at negative three, negative three.
- $821\ 00:48:49.230 \longrightarrow 00:48:52.380$ What we want to do is we want to explore this high density
- 822 00:48:52.380 --> 00:48:55.320 region of this bi-variate Gaussian,
- $823\ 00:48:55.320$ --> 00:49:00.233 and we slowly amble forward, and eventually we get there.
- $824\ 00:49:02.780 \longrightarrow 00:49:06.530$ But this algorithm breaks down in moderate dimensions.
- 825 00:49:06.530 --> 00:49:07.363 So.
- 826 00:49:11.390 --> 00:49:14.060 An algorithm that I think many of us are aware of
- 827 00:49:14.060 --> 00:49:16.040 at this point, that is kind of a workhorse
- $828\ 00:49:16.040 --> 00:49:17.800$ in high dimensional Bayesian inference
- 829 00:49:17.800 --> 00:49:19.880 is Hamiltonian Monte Carlo.
- $830\ 00{:}49{:}19.880 {\:-->\:} 00{:}49{:}23.900$ And this works by using actual gradient information about

- 831 00:49:23.900 --> 00:49:27.520 our log posterior in order to intelligently guide
- 832 00:49:27.520 --> 00:49:32.140 the MCMC proposals that we're making.
- 833 00:49:32.140 --> 00:49:34.230 So, again, let's just pretend that we start
- 834 00:49:34.230 --> 00:49:35.770 at negative three, negative three,
- $835\ 00:49:35.770 \longrightarrow 00:49:37.640$ but within a small number of steps,
- 836 00:49:37.640 --> 00:49:40.110 we're actually effectively exploring
- $837\ 00:49:40.110 \longrightarrow 00:49:43.520$ that high density region, and we're doing so
- $838\ 00:49:44.550 \longrightarrow 00:49:47.060$ because we're using that gradient information
- 839 00:49:47.060 --> 00:49:48.403 of the log posterior.
- 840 00:49:51.230 --> 00:49:55.930 I'm not going to go too deep right now into the formulation
- 841 00:49:55.930 --> 00:49:59.690 of Hamiltonian Monte Carlo, for the sake of time.
- 842 00:49:59.690 --> 00:50:04.220 But what I would like to point out,
- $843\ 00:50:04.220 --> 00:50:09.220$ is that after constructing this kind of physical system
- 844 00:50:13.462 \rightarrow 00:50:18.462 that is based on our target distribution
- $845\ 00:50:19.610 \longrightarrow 00:50:22.423$ on the posterior distribution, in some manner,
- $846\ 00{:}50{:}23.520 --> 00{:}50{:}28.520$ we actually obtain our proposals within the MCMC.
- $847\ 00:50:29.900$ --> 00:50:34.900 We obtain the proposals by simulating, by forward simulating
- $848\ 00:50:35.130$ --> 00:50:39.263 the physical system, according to Hamilton's equations.
- 849 00:50:40.400 --> 00:50:41.233 Now,
- $850\ 00{:}50{:}43.400 \dashrightarrow 00{:}50{:}48.210$ what this simulation involves is a massive number
- $851~00:50:48.210 \dashrightarrow 00:50:51.323$ of repeated gradient evaluations.
- $852\ 00:50:53.470$ --> 00:50:58.470 Moreover, if the posterior distribution is an ugly one,
- $853\ 00:50:59.770 \longrightarrow 00:51:03.963$ that is if it is still conditioned, which we interpret as,
- $854\ 00:51:05.670 \longrightarrow 00:51:09.090$ the log posterior Hessian has eigenvalues
- $855\ 00:51:09.090 \longrightarrow 00:51:11.526$ that are all over the place.

 $856\ 00{:}51{:}11.526 \dashrightarrow 00{:}51{:}16.526$ Then we can also use a mass matrix, M, which is gonna allow

 $857\ 00{:}51{:}16.828 {\: \hbox{--}}{>}\ 00{:}51{:}21.828$ us to condition our dynamics, and make sure that we are

 $858\ 00:51:23.610 \longrightarrow 00:51:27.023$ exploring all the dimensions of our model in an even manner.

 $859\ 00{:}51{:}29.120 \dashrightarrow 00{:}51{:}32.100$ So the benefit of Hamiltonian Monte-Carlo is that it scales

 $860\ 00:51:32.100 \longrightarrow 00:51:34.030$ to tens of thousands of parameters.

 $861~00{:}51{:}34.030 \dashrightarrow 00{:}51{:}38.130$ But the challenge is that that HMC necessitates repeated

862 00:51:38.130 --> 00:51:39.973 computation at the log likelihood,

 $863\ 00:51:42.433 \longrightarrow 00:51:44.957$ it's gradient and then preconditioning.

 $864\ 00:51:46.010 \longrightarrow 00:51:49.330$ And the best way that I know to precondition actually

 $865\ 00{:}51{:}49.330 --> 00{:}51{:}53.343$ involves evaluating the log likelihood Hessian as well.

 $866~00{:}51{:}54.840 --> 00{:}51{:}57.110$ And I told you that the challenges that I'm talking about

 $867\ 00:51:57.110 \longrightarrow 00:51:58.340$ today are intertwined.

 $868\ 00:51:58.340 \longrightarrow 00:52:00.973$ So what does this look like in a big data setting?

 $869~00{:}52{:}02.290 \dashrightarrow 00{:}52{:}06.370$ Well, we've already managed to speed up the log likelihood

 $870\ 00:52:06.370 --> 00:52:09.913$ computations that are quadratic in computational complexity.

871 00:52:11.120 --> 00:52:14.080 Well, it turns out that the log likelihood gradient

 $872\ 00:52:14.080 \longrightarrow 00:52:16.760$ and the log likelihood Hessian

 $873\ 00:52:16.760 --> 00:52:20.830$ are all quadratic and computational complexity.

 $874\ 00:52:20.830 \longrightarrow 00:52:24.410$ So this means that as the size of our data set grows,

 $875\ 00:52:24.410 \longrightarrow 00:52:25.760$ we're going to...

 $876\ 00{:}52{:}26.720 \dashrightarrow 00{:}52{:}31.000$ HMC, which is good at scaling to high dimensional models

877 00:52:31.000 --> 00:52:35.250 is going to break down because it's just gonna take too long

 $878\ 00{:}52{:}35.250 \dashrightarrow 00{:}52{:}38.513$ to evaluate the quantities that we need to evaluate.

879 00:52:42.510 --> 00:52:45.080 To show you exactly how these parallel

880 00:52:45.080 --> 00:52:47.603 gradient calculations can work.

881 00:52:50.630 --> 00:52:53.290 So, what am I gonna do?

882 00:52:53.290 --> 00:52:55.476 I'm gonna parallelize again on a GPU

883 00:52:55.476 --> 00:53:00.260 or a multi-core CPU implementation,

 $884\ 00:53:00.260 \longrightarrow 00:53:04.350$ and I'm interested in evaluating or obtaining

 $885\ 00:53:04.350 \longrightarrow 00:53:06.350$ the quantities in the red box.

 $886\ 00{:}53{:}06.350 \dashrightarrow 00{:}53{:}08.670$ These are simply the gradient of the log likelihood

 $887\ 00:53:08.670 \longrightarrow 00:53:11.263$ with respect to the individual rate parameters.

 $888\ 00:53:12.810 \rightarrow 00:53:16.780$ And because of the summation that it involves,

889 00:53:16.780 --> 00:53:20.520 we actually obtain in the left, top left,

 $890\ 00{:}53{:}20.520 \dashrightarrow 00{:}53{:}24.930$ we have the contribution of the first observation

 $891\ 00:53:24.930 \longrightarrow 00:53:28.010$ to that gradient term.

 $892\ 00{:}53{:}28.010 \dashrightarrow 00{:}53{:}30.780$ Then we have the contribution of the second observation

 $893\ 00:53:30.780 \longrightarrow 00:53:34.730$ all the way up to the big int observation,

 $894\ 00:53:34.730 --> 00:53:37.090$ that contribution to the gradient term.

 $895\ 00{:}53{:}37.090$ --> $00{:}53{:}40.970$ And these all need to be evaluated and summed over.

 $896\ 00:53:40.970 \longrightarrow 00:53:42.010$ So what do we do?

897 00:53:42.010 --> 00:53:44.710 We just do a running total, very simple.

898 $00:53:44.710 \longrightarrow 00:53:47.823$ We start by getting the first contribution.

 $899\ 00:53:48.790 \longrightarrow 00:53:51.593$ We keep that stored in place.

900 00:53:52.850 --> 00:53:55.560 We evaluate the second contribution,

901 00:53:55.560 --> 00:53:57.380 all at the same time in parallel,

 $902\ 00:53:57.380 --> 00:54:01.360$ and we simply increment our total observat-

- $903\ 00:54:01.360 --> 00:54:04.820$ excuse me, our total gradient by that value.
- 904 00:54:04.820 --> 00:54:05.810 Very simple.
- $905\ 00:54:05.810 \longrightarrow 00:54:07.373$ We do this again and again.
- $906\ 00:54:08.340 \longrightarrow 00:54:10.810$ Kind of complicated to program, to be honest.
- 907 00:54:10.810 --> 00:54:11.763 But it's simple.
- $908~00{:}54{:}15.812 \dashrightarrow 00{:}54{:}16.645$ It's simple when you think about it from the high level.
- 909 00:54:19.210 --> 00:54:21.370 So I showed you this figure before.
- 910 00:54:21.370 --> 00:54:24.060 And well, a similar figure before,
- 911 00:54:24.060 --> 00:54:25.630 and the interpretations are the same,
- 912 00:54:25.630 --> 00:54:29.910 but here I'll just focus on the question that I received.
- $913\ 00:54:29.910 \longrightarrow 00:54:32.060$ In the top left, we have the gradient.
- $914\ 00:54:32.060 \longrightarrow 00:54:33.870$ In the bottom left, excuse me,
- $915\ 00:54:33.870 \longrightarrow 00:54:35.160$ top row, we have the gradient.
- 916 00:54:35.160 --> 00:54:36.810 Bottom row, we have the Hessian,
- 917 00:54:36.810 --> 00:54:41.810 and here I'm increasing to 104 cores.
- 918 00:54:41.810 --> 00:54:45.970 So this is not infinite cores, right.
- 919 00:54:45.970 --> 00:54:47.320 It's 104.
- 920 00:54:47.320 --> 00:54:50.233 But I do want you to see that there's diminishing returns.
- 921 00:54:54.260 --> 00:54:57.480 And to give a little bit more technical
- 922 00:54:57.480 --> 00:54:59.093 response to that question,
- $923\ 00:55:01.530 \longrightarrow 00:55:03.940$ the thing to bear in mind is that
- 924 00:55:03.940 --> 00:55:07.700 it's not just about the number of threads that we use.
- 925 00:55:07.700 --> 00:55:12.170 It's having a lot of RAM very close
- $926\ 00:55:12.170 \longrightarrow 00:55:15.110$ to where the computing is being done.
- 927 00:55:15.110 --> 00:55:18.230 And that is something that GPUs,
- 928 00:55:18.230 --> 00:55:21.683 modern gigantic GPS do very well.
- 929 00:55:25.510 --> 00:55:28.470 So why is it important to do all this parallelization?

930 00:55:28.470 --> 00:55:31.890 Well, this is really, I want to kind of communicate

931 00:55:31.890 --> 00:55:34.453 this fact because it is so important.

932 00:55:36.227 --> 00:55:39.710 This slide underlines almost the entire challenge

933 00:55:39.710 --> 00:55:44.210 of big modeling using the spatiotemporal Hawkes process.

934 00:55:44.210 --> 00:55:49.210 The computing to apply this model to the 20,000 plus

935 00:55:49.420 --> 00:55:53.010 data points took about a month

936 00:55:53.950 --> 00:55:57.973 using a very large Nvidia GV100 GPU.

 $937\ 00:55:59.930 \longrightarrow 00:56:01.102$ Why?

938 00:56:01.102 --> 00:56:04.410 Because we had to generate 100 million Markov chain states

939 00:56:04.410 --> 00:56:07.993 at a rate of roughly three and a half million each day.

940 00:56:10.890 --> 00:56:14.940 After 100 million Markov chain states,

941 00:56:14.940 --> 00:56:18.303 after generating 100 million Markov chain states,

 $942\ 00:56:20.210 \longrightarrow 00:56:22.740$ this is the empirical distribution on the left

943 00:56:22.740 --> 00:56:25.633 of the effective sample sizes across,

944 00:56:27.910 --> 00:56:31.350 across all of the individual rates that we're inferring,

945 00:56:31.350 --> 00:56:33.050 actually all the model parameters.

946 00:56:34.130 --> 00:56:38.710 The minimum is 222, and that's right above my typical

947 00:56:38.710 --> 00:56:42.860 threshold of 200, because in general, we want the effective

948 00:56:42.860 --> 00:56:45.143 sample size to be as large as possible.

949 00:56:47.810 --> 00:56:50.350 Well, why was it so difficult?

950 00:56:50.350 --> 00:56:53.240 Well, a lot of the posterior,

 $951\ 00:56:53.240 \longrightarrow 00:56:55.330$ a lot of the marginal posteriors

 $952\ 00{:}56{:}55{.}330 \dashrightarrow 00{:}57{:}00{.}330$ for our different parameters were very complex.

 $953\ 00:57:00.650 --> 00:57:04.950$ So for example, here, I just have one individual rate.

954 00:57:04.950 \rightarrow 00:57:07.970 and this is the posterior that we learned from it.

955 00:57:07.970 --> 00:57:08.893 It's bi-modal.

956 00:57:09.960 --> 00:57:11.290 And not only is it bi-modal,

 $957\ 00:57:11.290 --> 00:57:14.113$ but the modes exist on very different scales.

958~00:57:15.640 --> 00:57:19.300 Well, why else is it a difficult posterior to sample from?

959 00:57:19.300 --> 00:57:21.640 Well, because actually, as you might imagine,

960 00:57:21.640 --> 00:57:25.403 these rates have a very complex correlation in structure.

961 00:57:27.753 --> 00:57:29.880 This is kind of repeating something that I said earlier

 $962\ 00:57:29.880 \longrightarrow 00:57:32.623$ when we were actually inferring locations,

963 00:57:33.470 --> 00:57:36.330 which is that what this amounts to is really simulating

964 00:57:36.330 --> 00:57:38.593 a very large n-body problem.

965 00:57:43.750 --> 00:57:45.040 But what's the upshot?

 $966\ 00:57:45.040 \longrightarrow 00:57:50.040$ Well, we can actually capture these individual rates,

967 00:57:50.730 --> 00:57:55.150 which could give us hints at where to look for certain

 $968\ 00{:}57{:}55.150 \dashrightarrow 00{:}58{:}00.150$ mutations that are allowing, say in this example,

 $969\ 00:58:00.600 \longrightarrow 00:58:03.203$ the Ebola virus to spread more effectively.

970 00:58:04.560 --> 00:58:08.790 And here, red is generally the highest,

971 00:58:08.790 --> 00:58:10.683 whereas blue is the lowest.

 $972\ 00:58:13.270 \longrightarrow 00:58:14.990$ We can get credible intervals,

973 00:58:14.990 --> 00:58:17.740 which can give us another way of thinking about, you know,

974 00:58:17.740 --> 00:58:19.010 where should I be looking

 $975\ 00:58:22.258 --> 00:58:26.347$ in this collection of viral samples, for the next big one?

 $976~00:58:28.643 \longrightarrow 00:58:31.890$ And then I can also ask, well, how do these rates actually

977 00:58:31.890 --> 00:58:36.890 distribute along the phylogenetic tree?

978 00:58:37.170 --> 00:58:41.010 So I can look for clades or groups of branches

979 00:58:41.010 \rightarrow 00:58:45.577 that are in general, more red in this case than others.

980 $00:58:53.270 \longrightarrow 00:58:55.080$ So, something that I...

981 00:58:55.080 --> 00:58:58.143 Okay, so it's 10 o'clock, and I will finish in one slide.

982 00:59:02.610 --> 00:59:04.980 The challenges that I'm talking about today,

 $983\ 00:59:04.980 \longrightarrow 00:59:07.700$ they're complex and they're intertwined,

 $984\ 00:59:07.700 \longrightarrow 00:59:09.720$ but they're not the only challenges.

985 00:59:09.720 --> 00:59:14.000 There are many challenges in the application

986 00:59:14.000 --> 00:59:16.370 of spatiotemporal Hawkes models,

 $987\ 00:59:16.370 \longrightarrow 00:59:18.673$ and there's actually a very large literature.

988 $00:59:21.100 \longrightarrow 00:59:24.560$ So some other challenges that we might consider,

 $989\ 00{:}59{:}24.560 {\:{\mbox{--}}}{>}\ 00{:}59{:}29.560$ and that will also be extremely challenging to overcome

990 $00:59:31.270 \longrightarrow 00:59:32.350$ in a big data setting.

991 00:59:32.350 --> 00:59:37.253 So, kind of the first challenge is flexible modeling.

992 00:59:38.150 --> 00:59:40.860 So here, we want to use as flexible

993 $00:59:40.860 \longrightarrow 00:59:43.940$ of a Hawkes model as possible.

994 00:59:43.940 --> 00:59:48.940 And this challenge kind of encapsulates one of the great

 $995~00:59:49.460 \longrightarrow 00:59:54.210$ ironies of model-based nonparametrics, which is that,

 $996\ 00:59:55.300 \longrightarrow 00:59:58.020$ the precise time that we actually want to use

997 00:59:58.020 --> 01:00:01.203 a flexible model, is the big data setting.

998 01:00:03.410 --> 01:00:07.200 I mean, I don't know if you recall my earlier slide

999 01:00:07.200 \rightarrow 01:00:09.600 where I was showing the posterior distribution

 $1000\ 01:00:09.600 \longrightarrow 01:00:12.850$ of some of the length scales associated with

 $1001\ 01:00:12.850 --> 01:00:17.673$ the Washington DC data, and they're extremely tight.

 $1002\ 01{:}00{:}19.190 {\:{\mbox{--}}\!>} 01{:}00{:}23.620$ But this is actually exactly where we'd want to be able

 $1003\ 01:00:23.620 --> 01:00:28.180$ to use a flexible model, because no matter what,

1004 01:00:28.180 --> 01:00:31.640 if I apply my model to 85,000 data points,

1005 01:00:31.640 --> 01:00:36.240 I'm going to be very certain in my conclusion,

 $1006~01:00:36.240 \dashrightarrow 01:00:38.823$ conditioned on the specific model that I'm using.

1007 01:00:40.520 --> 01:00:43.000 There's also boundary issues, right.

1008 01:00:43.000 --> 01:00:44.640 This is a huge, a huge thing.

 $1009\ 01:00:44.640 \longrightarrow 01:00:47.030$ So for those of you that are aware

 $1010\ 01:00:47.030 \longrightarrow 01:00:50.703$ of the survival literature, which I'm sure many of you are,

1011 01:00:51.720 --> 01:00:53.940 you know, they're censoring.

 $1012\ 01:00:53.940 \dashrightarrow 01:00:56.740$ So what about gunshots that occurred right outside

 $1013\ 01:00:56.740$ --> 01:01:00.700 of the border of Washington DC, and it occurred as a result

 $1014\ 01:01:00.700 \longrightarrow 01:01:03.280$ of gunshots that occurred within the border?

 $1015\ 01:01:03.280 \longrightarrow 01:01:05.330$ And then we can flip that on its head.

 $1016~01{:}05.330 \dashrightarrow 01{:}01{:}10.100$ What about parent events outside of Washington DC

 $1017\ 01:01:10.100$ --> 01:01:13.450 that precipitated gun violence within Washington DC.

 $1018\ 01:01:13.450 \longrightarrow 01:01:15.710$ And then finally, sticking with the same example,

 $1019\ 01:01:15.710 --> 01:01:16.810$ differential sampling.

 $1020\ 01{:}01{:}20.120 \dashrightarrow 01{:}01{:}25.120$ You can be certain that those acoustic gunshot locators,

 $1021\ 01:01:26.880 --> 01:01:30.320$ location system sensors are not planted

 $1022\ 01:01:30.320 \longrightarrow 01:01:32.343$ all over Washington DC.

 $1023\ 01{:}01{:}34.210$ --> $01{:}01{:}36.603$ And how does their distribution affect things?

1024 01:01:41.010 --> 01:01:41.843 Okay.

 $1025\ 01:01:41.843$ --> 01:01:44.550 This is joint work with Mark Suchard at UCLA, also at UCLA.

1026 01:01:44.550 --> 01:01:46.530 And then my very good friend,

 $1027\ 01:01:46.530 --> 01:01:49.990$ my very dear friend, Xiang Ji at Tulane.

 $1028~01{:}01{:}49.990 \dashrightarrow 01{:}01{:}54.240$ It's funded by the K-Award Big Data Predictive Phylogenetics

1029 01:01:54.240 --> 01:01:57.840 with Bayesian learning, funded by the NIH.

1030 01:01:57.840 --> 01:01:58.920 line:15% And that's it.

 $1031\ 01:01:58.920 \longrightarrow 01:01:59.753\ \text{line}:15\%$ Thank you.

1032 01:02:05.640 --> 01:02:06.685 <-v Man>All right.</v>

 $1033\ 01:02:06.685 --> 01:02:07.950$ Thank you so much, Professor Holbrook.

1034 01:02:07.950 --> 01:02:11.349 Does anybody have any other questions?

1035 01:02:11.349 --> 01:02:15.266 (people speaking indistinctly)

 $1036\ 01:02:18.070 \longrightarrow 01:02:18.903$ Yeah.

 $1037\ 01:02:20.970 \longrightarrow 01:02:25.316$ Any other questions from the room here, or from Zoom?

1038 01:02:25.316 --> 01:02:27.375 (people speaking indistinctly)
