## WEBVTT

 $1 \ 00:00:00.330 \longrightarrow 00:00:01.500 < v \longrightarrow And welcome. </v >$ 

2 00:00:01.500 --> 00:00:02.553 Today, it's my, eh.

3 00:00:04.500 --> 00:00:09.180 Today, it is my pleasure to introduce Professor Abhi Datta

4 00:00:09.180 --> 00:00:13.320 from Johns Hopkins University in Baltimore, Maryland.

 $5~00{:}00{:}13.320 \dashrightarrow 00{:}00{:}15.480$  Professor Datta earned his BS and MS

6 00:00:15.480 --> 00:00:17.310 from the Indian Statistical Institute

7 00:00:17.310 --> 00:00:20.340 in 2008 and 2010 respectively,

800:00:20.340 --> 00:00:24.540 and PhD from the University of Minnesota in 2016.

 $9\ 00:00:24.540 \longrightarrow 00:00:26.640$  In addition to being a well-cited researcher

10 00:00:26.640 --> 00:00:29.670 with one publication that's almost 600 citations,

11 00:00:29.670  $\rightarrow 00:00:30.813$  which is pretty nice,

12 00:00:31.860 --> 00:00:34.560 he's also a award-winning educator,

 $13\ 00{:}00{:}34{.}560$  -->  $00{:}00{:}37{.}200$  having repeatedly won an excellence in teaching award

14 00:00:37.200 --> 00:00:38.820 from his institution.

15 00:00:38.820 --> 00:00:40.413 So let's welcome Dr. Datta.

16 00:00:44.310 --> 00:00:45.143 <v ->Thank you, Robert,</v>

17 00:00:45.143 --> 00:00:47.940 for the invitation to come here and give the seminar,

 $18\ 00:00:47.940$  --> 00:00:50.070 and for the very nice introduction.

19 $00:00:50.070 \dashrightarrow 00:00:51.570$  Thank you everyone for coming.

20 $00{:}00{:}52.440 \dashrightarrow 00{:}00{:}56.310$  My talk is about improving cause-specific mortality data

21 $00{:}00{:}56{.}310 \dashrightarrow 00{:}00{:}58{.}290$  in low and middle-income countries

22 $00{:}00{:}58.290 \dashrightarrow 00{:}01{:}00.090$  where the main tool to collect data

23 $00{:}01{:}00.090 \dashrightarrow 00{:}01{:}02.280$  is something called verbal autopsies.

24 00:01:02.280 --> 00:01:03.150 And the way I do it

 $25\ 00:01:03.150$  --> 00:01:06.510 is using a statistical approach called generalized Bayes.

 $26\ 00:01:06.510 \longrightarrow 00:01:07.770$  If you have not heard

27 00:01:07.770 --> 00:01:10.710 of verbal autopsies or generalized Bayes,

28 00:01:10.710 --> 00:01:14.130 I can tell you that I hadn't heard of either of those things

29 00:01:14.130 --> 00:01:16.590 when I started working on the project,

 $30\ 00:01:16.590 \longrightarrow 00:01:17.760$  so don't worry about that,

31 00:01:17.760 --> 00:01:20.280 I try to give an introduction.

32 00:01:20.280 --> 00:01:23.970 'Cause I mostly work on a spatial and spatial temporal data

 $33\ 00:01:23.970 \longrightarrow 00:01:26.503$  and this was a project that came along,

34 00:01:26.503 --> 00:01:28.830 which is very different from what I used to work on.

 $35\ 00{:}01{:}28.830 \dashrightarrow 00{:}01{:}31.410$  But over the years, there's been a nice body of work

 $36\ 00:01:31.410 \longrightarrow 00:01:33.033$  developed in this project.

 $37\ 00:01:35.310 \longrightarrow 00:01:37.630$  So this is a joint work

38 00:01:38.914 --> 00:01:43.710 with many different institutes and collaborators.

39 00:01:43.710 --> 00:01:46.230 The top row is the Hopkins bio stats team,

 $40\ 00:01:46.230 \longrightarrow 00:01:48.300$  which included my former students,

41 00:01:48.300 --> 00:01:50.700 Jacob Fiksel and Brian Gilbert,

42 00:01:50.700 --> 00:01:53.310 and my current postdoc, Sandi,

43 00:01:53.310 --> 00:01:56.280 and my colleague, Scott Zeger, and I

44 00:01:56.280 --> 00:01:58.263 lead the bio stats part of the team.

 $45\ 00:02:00.073 \longrightarrow 00:02:03.450$  Agbessi is the PI of the project in Mozambique

46 00:02:03.450 --> 00:02:07.440 that's sort of picked up developments for this work.

 $47\ 00:02:07.440 \longrightarrow 00:02:08.670$  And there are a lot of colleagues

48 00:02:08.670 --> 00:02:10.260 from the International Health Department

49 00:02:10.260 --> 00:02:12.120 that helped to collaborate.

 $50\ 00:02:12.120 \longrightarrow 00:02:15.536$  And then Li is the PI of a new project

 $51\ 00:02:15.536 \longrightarrow 00:02:17.430$  who we're going to apply our methodology

 $52\ 00:02:17.430 \longrightarrow 00:02:21.660$  for producing mortality estimates for the WHO.

53  $00:02:21.660 \rightarrow 00:02:24.570$  So we're collaborating with Li there as well.

 $54\ 00:02:24.570 \longrightarrow 00:02:27.360$  And then a couple of people outside Hopkins,

55 00:02:27.360 --> 00:02:30.930 Dianna at CDC and Emory University,

56 00:02:30.930  $\rightarrow$  00:02:34.530 as the director of the CHAMPS project.

57 00:02:34.530 --> 00:02:38.730 And Ivalda in the government body at Mozambique

58 00:02:38.730 --> 00:02:41.670 has been now currently doing the work in Mozambique.

 $59\ 00:02:43.770$  --> 00:02:48.770 So this is funded by three grants from the Gates Foundation.

 $60\ 00{:}02{:}48.840 \dashrightarrow 00{:}02{:}51.840$  The first one was the grant that kind of started things.

61 00:02:51.840 --> 00:02:55.020 And then we have a grant that is kind of developing more

 $62\ 00:02:55.020 \longrightarrow 00:02:56.620$  on the method side of the world.

63 00:02:58.860 --> 00:03:03.640 So, many low and middle-income countries

 $64\ 00:03:04.920 \longrightarrow 00:03:08.400$  often lack high-quality data on causes of death.

 $65\ 00:03:08.400 \longrightarrow 00:03:09.630$  Often for most deaths,

 $66\ 00:03:09.630 \longrightarrow 00:03:13.380$  there is no sort of medical certification

67 00:03:13.380 --> 00:03:16.170 or like an autop<br/>sy done.

68 00:03:16.170 --> 00:03:18.600 And without kind of high-quality data

 $69\ 00:03:18.600 \longrightarrow 00:03:20.880$  on what people are dying of,

 $70\ 00:03:20.880 \longrightarrow 00:03:22.890$  it's kind of hard to estimate the disease burden

71 00:03:22.890 --> 00:03:23.943 in these countries.

 $72\ 00:03:24.960 \longrightarrow 00:03:27.090$  And specifically, the quantity of interest

 $73\ 00:03:27.090 \longrightarrow 00:03:29.070$  is the cause-specific mortality fraction,

74 00:03:29.070 --> 00:03:33.930 which is basically the percentage of deaths in a age group

 $75\ 00:03:33.930 \longrightarrow 00:03:36.303$  that can be attributable to a given cause.

76 00:03:37.740  $\rightarrow 00:03:39.510$  So cause-specific mortality fractions

 $77\ 00:03:39.510 \longrightarrow 00:03:41.940$  are key pieces of information

 $78\ 00:03:41.940 \longrightarrow 00:03:44.070$  in determining the global burden of disease,

 $79\ 00:03:44.070 \longrightarrow 00:03:46.620$  which in turn dictates sovereign policy,

 $80\ 00:03:46.620$  --> 00:03:49.170 as well as like resource allocations

 $81\ 00:03:49.170 \longrightarrow 00:03:51.273$  for programs operating in this country.

 $82 \ 00:03:54.480 \longrightarrow 00:03:56.580$  So verbal autopsy is an alternate way

83 00:03:56.580  $\rightarrow$  00:03:58.770 to count deaths and attribute causes

 $84\ 00:03:58.770 \longrightarrow 00:04:02.130$  without actually doing a clinical autopsy.

 $85\ 00:04:02.130 \longrightarrow 00:04:04.320$  So verbal autopsy is basically

 $86\ 00:04:04.320 \longrightarrow 00:04:06.720$  a sort of a systematic interview

 $87\ 00:04:06.720 \longrightarrow 00:04:08.340$  of the household members of the deceased.

 $88\ 00{:}04{:}08{.}340 \dashrightarrow 00{:}04{:}11.760$  So the government or the program has a set of field workers

 $89\ 00:04:11.760 \longrightarrow 00:04:14.580$  who go out and go from household to household

90 00:04:14.580 --> 00:04:16.530 and ask if anyone died in their household

 $91\ 00:04:16.530 \longrightarrow 00:04:18.120$  within the last several months.

92 00:04:18.120 --> 00:04:19.920 And if they died, what were the symptoms?

93 00:04:19.920 --> 00:04:22.770 And the set of questions they ask is not standardized

94 00:04:22.770 --> 00:04:24.360 by the WHO.

 $95\ 00:04:24.360 \longrightarrow 00:04:26.610$  Some example questions are here.

96 00:04:26.610 --> 00:04:29.190 Most of the questions would have binary answers

97 00:04:29.190  $\rightarrow$  00:04:31.530 like yes, no, but there are some questions

98 00:04:31.530 --> 00:04:35.793 that have more like continuous responses.

99 00:04:38.430 $\operatorname{-->}$ 00:04:40.530 So they said the WHO has standardized

 $100\ 00:04:40.530 \longrightarrow 00:04:41.730$  the verbal autopsy tool.

101 00:04:42.990 --> 00:04:46.530 The 2016 version has around 200 to 350 questions,

 $102\ 00:04:46.530 \longrightarrow 00:04:48.360$  depending on the age group.

103 00:04:48.360 --> 00:04:50.220 There are separate sections of the questionnaire

 $104\ 00:04:50.220$  --> 00:04:53.880 for neonates, children deaths and adult deaths.

105 00:04:53.880 --> 00:04:55.770 And if you're interested in more information 106 00:04:55.770 --> 00:05:00.063 about verbal autopsy, there's a page in WHO about it.

107 00:05:01.560 --> 00:05:03.720 So a verbal autopsy, of course,

 $108\ 00:05:03.720 \longrightarrow 00:05:05.070$  doesn't give you a cause of death,

109 $00{:}05{:}05{.}070 \dashrightarrow 00{:}05{:}07.620$  it just gives you a bunch of yes-no responses

 $110\ 00:05:07.620 \longrightarrow 00:05:10.233$  to various questions related to the symptoms.

111 00:05:14.325 --> 00:05:17.187 So a verbal autopsy is basically a survey questionnaire.

112 00:05:17.187 --> 00:05:19.710 So you can pass that survey through a computer software

113  $00:05:19.710 \rightarrow 00:05:22.740$  and that can give a predictive cause of death.

114 00:05:22.740 --> 00:05:23.700 And so there are a bunch

115 00:05:23.700  $\rightarrow$  00:05:26.163 of different computer software available.

116 00:05:27.120 --> 00:05:30.540 InSilicoVA, developed by Tyler McCormick,

117 00:05:30.540 --> 00:05:32.403 Richard Li was a postdoc here,

118 00:05:33.750 --> 00:05:36.240 is published in "JASA" in 2016,

 $119\ 00:05:36.240 \longrightarrow 00:05:37.440$  is one of the, I think,

120 00:05:37.440 --> 00:05:39.900 most statistically-principled approaches to do it.

121 00:05:39.900 --> 00:05:42.660 But there are other approaches and then you can,

 $122\ 00:05:42.660 \longrightarrow 00:05:44.700$  this is basically a classification problem.

123 00:05:44.700 --> 00:05:47.700 So you're basically given your data on symptoms,

124 $00{:}05{:}47.700 \dashrightarrow 00{:}05{:}50.000$  you're kind of classifying the cause of death

 $125\ 00:05:50.000 \longrightarrow 00:05:51.420$  as one of several causes.

 $126\ 00:05:51.420 \longrightarrow 00:05:54.420$  So you can use standard classifiers

 $127 \ 00:05:54.420 \longrightarrow 00:05:56.420$  and machine learning approaches as well.

128 00:05:57.606 --> 00:05:59.010 OpenVA is an excellent resource

 $129\ 00:05:59.010 \longrightarrow 00:06:00.480$  to learn about verbal autopsies.

 $130\ 00:06:00.480 \longrightarrow 00:06:02.943$  Again, openVA is,

131 00:06:03.811  $\rightarrow 00:06:05.520$  I think Richard is one of the maintainers

 $132\ 00:06:05.520 \longrightarrow 00:06:06.693$  and creators of openVA.

133 00:06:11.400 --> 00:06:14.040 So the COMSA project in Mozambique,

 $134\ 00:06:14.040 \longrightarrow 00:06:16.710$  one of the main goals was to generate

135 00:06:16.710  $\rightarrow$  00:06:19.440 this cause-specific mortality fractions

 $136\ 00:06:19.440 \longrightarrow 00:06:21.360$  for children's and under,

137 00:06:21.360 --> 00:06:23.160 for neonates and under-five children

 $138\ 00:06:24.360 \longrightarrow 00:06:26.250$  for the country of Mozambique.

139 00:06:26.250 --> 00:06:30.300 And the data that we collected was a large dataset

140 00:06:30.300 --> 00:06:32.037 of vocal autopsy record

141  $00:06:32.037 \rightarrow 00:06:34.080$  for different households that were surveyed

142 00:06:34.080 --> 00:06:37.860 and that was a map of Mozambique

 $143\ 00:06:37.860 \longrightarrow 00:06:41.080$  and the green region show

144 00:06:41.080 --> 00:06:42.960 where the data was collected

 $145\ 00:06:42.960 \longrightarrow 00:06:44.370$  as part of the COMSA project.

146 00:06:44.370 --> 00:06:49.370 So in statistical terms, the data just has the symptoms,

 $147\ 00:06:49.380 \longrightarrow 00:06:50.970$  it doesn't have the true cause of death,

 $148\ 00:06:50.970 \longrightarrow 00:06:52.863$  so we call it the unlabeled data.

149 $00{:}06{:}56{.}970 \dashrightarrow 00{:}07{:}00{.}060$  So how to go from an unlabeled data to the labeling

150 00:07:00.060 --> 00:07:01.491 of the causes of death

151  $00:07:01.491 \rightarrow 00:07:03.720$  and then estimate these cause fractions.

 $152\ 00:07:03.720$  --> 00:07:07.755 This is the standard procedure that is typically done

153 00:07:07.755 --> 00:07:09.870 and this is what we were supposed to do as well,

 $154\ 00:07:09.870 \longrightarrow 00:07:12.300$  which is simply take each record,

155 00:07:12.300  $\rightarrow 00:07:14.430$  pass it through the computer software

156 00:07:14.430 --> 00:07:16.050 and get a cause of death.

157 00:07:16.050 --> 00:07:17.580 And once you get a cause of death,

158 00:07:17.580  $\rightarrow 00:07:19.440$  then you can sort of simply aggregate.

 $159\ 00:07:19.440 \longrightarrow 00:07:21.210$  So in the story example,

160 00:07:21.210 --> 00:07:24.930 three out of the six cases were assigned to be from HIV.

161 00:07:24.930 --> 00:07:27.390 And so the cause-specific mortality fraction for HIV

162 00:07:27.390 --> 00:07:31.950 would be 50% and similar for malaria and sepsis and so on.

 $163\ 00:07:31.950 \longrightarrow 00:07:35.160$  So that's the basic template

164 00:07:35.160 --> 00:07:37.590 of how to get a cause-specific mortality fractions

 $165\ 00:07:37.590 \longrightarrow 00:07:39.060$  from verbal autopsies.

166 00:07:39.060  $\rightarrow$  00:07:41.010 The question is can we trust this estimates?

167 $00:07:41.010 \dashrightarrow 00:07:42.960$  Because these are not true causes of death

168 00:07:42.960 --> 00:07:45.900 as determined by a doctor or by a clinical procedure.

169 00:07:45.900 --> 00:07:48.300 These are cause of death predicted by an algorithm

170 00:07:48.300 --> 00:07:52.140 based on just surveying the household members

 $171\ 00:07:52.140 \longrightarrow 00:07:53.103$  of the deceased.

172 00:07:57.295  $\rightarrow 00:07:59.730$  So turns out machine learning has a name

 $173\ 00:07:59.730 \longrightarrow 00:08:01.020$  for this type of problems,

174 00:08:01.020 --> 00:08:03.630 it's called quantification learning,

 $175\ 00:08:03.630$  --> 00:08:06.870 which is basically estimating population prevalence

176  $00:08:06.870 \rightarrow 00:08:09.900$  using predicted levels instead of true levels

177 00:08:09.900 --> 00:08:12.570 and the predictions are coming from a classifier.

178 00:08:12.570 --> 00:08:15.510 And so there has been some work in quantification learning

179 00:08:15.510  $\rightarrow 00:08:18.900$  and in the machine learning literature.

 $180\ 00:08:18.900 --> 00:08:20.640$  So when we were working on this problem,

 $181\ 00:08:20.640 \longrightarrow 00:08:21.960$  we realized that estimating

 $182\ 00:08:21.960 \longrightarrow 00:08:23.760$  cause-specific mortality fractions

183 00:08:23.760 --> 00:08:26.760 using predicted cause of death data from verbal autopsy

 $184\ 00:08:26.760 \longrightarrow 00:08:28.953$  is an example of quantification learning.

185 00:08:30.690 --> 00:08:34.620 So just a sort of an overview of terms that we'll be using

186  $00:08:34.620 \rightarrow 00:08:36.570$  and the corresponding statistical notation.

187 00:08:36.570 --> 00:08:41.570 So our true cause of death is y which we do not observe.

 $188\ 00:08:41.760 --> 00:08:43.310$  We want to estimate the probability

189 00:08:43.310 --> 00:08:45.330 of population prevalence of y,

 $190\ 00:08:45.330 \longrightarrow 00:08:47.433$  so y is a categorical variable.

191 00:08:48.510 --> 00:08:50.640 And so probability of y or p

192 $00:08:50.640 \dashrightarrow 00:08:52.770$  is our cause-specific mortality fraction,

193 00:08:52.770 --> 00:08:54.780 which is the estimand.

 $194\ 00:08:54.780 \longrightarrow 00:08:57.390$  We observed the verbal autopsy, which is a,

 $195\ 00:08:57.390 \longrightarrow 00:09:00.180$  think of this as a high dimensional

196 00:09:00.180 --> 00:09:01.740 or a long list of yes-no answers

197 00:09:01.740  $\rightarrow$  00:09:05.850 to the verbal autopsy questions, so that is x,

 $198\ 00:09:05.850 \longrightarrow 00:09:08.010$  and this x is passed through a software

199 00:09:08.010 --> 00:09:11.913 to give a predicted level, which is a of x or simply a.

 $200\ 00:09:17.070 \longrightarrow 00:09:21.060$  So what we have in the COMSA project

201 00:09:21.060 --> 00:09:24.600 is simply an unlabeled dataset

 $202\ 00:09:24.600 \rightarrow 00:09:28.350$  which uses these verbal autopsy responses,

203 00:09:28.350 --> 00:09:33.350 pass it through a software and get the predicted levels.

 $204\ 00:09:33.510 \longrightarrow 00:09:36.870$  We do not observe the true levels, y,

 $205\ 00:09:36.870$  --> 00:09:40.170 we may or may not retain the verbal autopsy responses

206 $00{:}09{:}40.170 \dashrightarrow 00{:}09{:}41.790$  because those are identifiable data

 $207\ 00:09:41.790 \longrightarrow 00:09:43.290$  and those are often not released,

20800:09:43.290 --> 00:09:46.500 so often, just the predicted cause of that is available.

209 00:09:46.500 --> 00:09:50.070 So even these covariates, x, may or may not be available.

210 00:09:50.070 --> 00:09:53.340 And then we are interested in estimating the probability

211 00:09:53.340 --> 00:09:57.720 that y belongs to one of the C many cause categories,

 $212\ 00:09:57.720 \longrightarrow 00:09:59.913$  so that's a quantity of interest.

213 00:10:05.160 --> 00:10:07.470 For some reason, there is a conditional sign

 $214\ 00:10:07.470 \longrightarrow 00:10:09.090$  that's missing there.

215 00:10:09.090 --> 00:10:13.080 But you can use the law of total probability

 $216\ 00{:}10{:}13.080 \dashrightarrow 00{:}10{:}16.050$  to write the probability of the predicted cause of death,

217 00:10:16.050 --> 00:10:17.610 which is the a,

218 00:10:17.610 --> 00:10:22.020 probability of a as a sum of our probability of a given y

 $219\ 00:10:22.020 \longrightarrow 00:10:24.150$  times probability of y.

 $220\ 00:10:24.150 \longrightarrow 00:10:26.190$  So there's a conditional sign missing here,

221 00:10:26.190 --> 00:10:28.190 I don't don't know what's going on here.

 $222\ 00:10:32.010 \longrightarrow 00:10:33.180$  But the COMSA data,

223 00:10:33.180 --> 00:10:36.090 we only get information on the left-hand side, right?

224 00:10:36.090 --> 00:10:40.770 And we want to input upon the quantity probability of y

 $225\ 00:10:40.770 \longrightarrow 00:10:42.863$  which would be the true CSMFs.

 $226\ 00:10:44.031 \longrightarrow 00:10:45.960$  So there is only one known quantity

227 00:10:45.960 --> 00:10:48.193 with which you can estimate the left-hand side.

228 00:10:48.193 --> 00:10:50.010 There are two unknown quantities on the right-hand side.

229 00:10:50.010 --> 00:10:53.820 So without making assumptions, you cannot really identify

230 00:10:53.820 --> 00:10:55.950 probability of y, right?

 $231\ 00:10:55.950 \longrightarrow 00:10:58.530$  So any quantification learning methods

 $232\ 00{:}10{:}58{.}530 \dashrightarrow 00{:}11{:}01{.}620$  need to either estimate those conditional probabilities,

233 00:11:01.620 --> 00:11:03.510 probability of a given y,

 $234\ 00:11:03.510 \longrightarrow 00:11:05.133$  or make some assumptions on it.

 $235\ 00:11:07.680 \longrightarrow 00:11:12.680$  So again, all the conditional signs are missing.

 $236\ 00:11:16.410 \longrightarrow 00:11:18.990$  The one of the most common approaches,

237 00:11:18.990 --> 00:11:22.170 and this is what is used in the verbal autopsy world

 $238\ 00:11:22.170 \longrightarrow 00:11:24.540$  is called classify and count,

239 00:11:24.540 --> 00:11:27.930 which is you simply predict the cause of death 240 00:11:27.930 --> 00:11:29.220 and then aggregate.

241 00:11:29.220 --> 00:11:33.439 So you're simply claiming that probability of a

242 00:11:33.439 --> 00:11:36.420 is same as probability of **y** which is equivalent to claiming

243 00:11:36.420  $\rightarrow$  00:11:38.850 that this misclassification rate matrix

 $244\ 00:11:38.850 \longrightarrow 00:11:41.310$  is an identity matrix, right?

245 00:11:41.310 --> 00:11:43.740 Because you're saying that the left hand quantity

246 00:11:43.740 --> 00:11:47.530 is the same as the rightmost quantity, which would be true

 $247\ 00:11:48.390 \longrightarrow 00:11:50.760$  if there is no misclassification by the algorithm

 $248\ 00:11:50.760 \longrightarrow 00:11:52.680$  and if the predicted cause of death

 $249\ 00:11:52.680 \longrightarrow 00:11:54.423$  is always the true cause of death.

 $250\ 00:11:55.860 \longrightarrow 00:11:58.110$  And that's what is typically done

251 00:11:58.110 --> 00:12:01.890 in this cause-specific mortality fraction estimates.

252 00:12:01.890 --> 00:12:03.630 But it's a very strong assumption, right?

253 00:12:03.630 --> 00:12:07.200 Because it says assuming perfect sensitivity and specificity

254 00:12:07.200 --> 00:12:08.050 of the algorithm.

255 00:12:09.570 --> 00:12:11.880 So let's look at how perfect the algorithms are.

 $256\ 00:12:11.880 \longrightarrow 00:12:13.320$  So these are two algorithms,

257 00:12:13.320 --> 00:12:15.510 Tariff and InSilicoVA,

258 00:12:15.510 --> 00:12:19.950 PHMRC data is a benchmark dataset from four countries

 $259\ 00:12:19.950 \longrightarrow 00:12:21.870$  that has both the verbal autopsy data

260 00:12:21.870 --> 00:12:26.250 as well as a gold standard cause of death diagnosis.

261 00:12:26.250 --> 00:12:30.000 And you can see the accuracies of either method

 $262\ 00:12:30.000 \longrightarrow 00:12:32.940$  is around 30%, so they're far from being

263 00:12:32.940 --> 00:12:34.443 like fully accurate.

 $264\ 00:12:35.850 \longrightarrow 00:12:39.330$  So there is large misclassification rates

265 00:12:39.330 --> 00:12:41.790 of these algorithms and if you don't kind of adjust

 $266\ 00:12:41.790 \longrightarrow 00:12:44.430$  for these misclassifications,

 $267\ 00:12:44.430 \longrightarrow 00:12:45.540$  this is burden estimates

268 00:12:45.540 --> 00:12:48.480 of the cause-specific mortality fractions you get

 $269\ 00:12:48.480 \longrightarrow 00:12:50.230$  are likely going to be very biased.

270 00:12:53.610 --> 00:12:57.660 So this is where the CHAMPS project comes into play.

271 00:12:57.660 --> 00:13:00.090 So the CHAMPS is an ongoing project

272 00:13:00.090 --> 00:13:04.650 in like seven or eight countries including Mozambique,

 $273\ 00:13:04.650 \longrightarrow 00:13:07.380$  which is collecting data on both verbal autopsy  $274\ 00:13:07.380 \longrightarrow 00:13:11.310$  and a more comprehensive cause of death

procedure

 $275\ 00:13:11.310 \longrightarrow 00:13:13.830$  called minimally invasive tissue sampling.

276 00:13:13.830 --> 00:13:17.490 So it basically takes a sample of your tissue

 $277\ 00:13:17.490 \longrightarrow 00:13:20.460$  of the deceased person and then runs a bunch

 $278 \ 00:13:20.460 \longrightarrow 00:13:23.070$  of pathological tests and imaging analysis

 $279\ 00:13:23.070 \longrightarrow 00:13:25.410$  and then gives a cause of death.

280 00:13:25.410 --> 00:13:29.080 And the MITS cause of death assignments

281 00:13:30.330 --> 00:13:32.790 have been shown to be quite accurate when you compare

282 00:13:32.790 --> 00:13:34.593 to like a full diagnostic autopsy.

283 00:13:36.210 --> 00:13:37.920 So MITS is being done in a bunch

284 00:13:37.920 --> 00:13:40.950 of different countries including Mozambique.

 $285\ 00:13:40.950 \longrightarrow 00:13:43.380$  And for the cases where MITS is being done,

 $286\ 00:13:43.380 \longrightarrow 00:13:45.990$  the verbal autopsies are also collected.

287 00:13:45.990 --> 00:13:48.120 So what you get from this CHAMPS data

 $288\ 00:13:48.120 \longrightarrow 00:13:50.310$  is a labeled or paired dataset

 $289\ 00:13:50.310 \longrightarrow 00:13:51.930$  where you have both the verbal autopsy

290 00:13:51.930 --> 00:13:54.000 as well as the MITS cause of death

291 00:13:54.000 --> 00:13:57.630 and you can pass the verbal autopsy to the software

292 00:13:57.630 --> 00:14:00.254 to get the verbal autopsy predicted cause of death.

 $293\ 00:14:00.254 \longrightarrow 00:14:01.770$  And then you can cross tabulate the two

294 00:14:01.770 --> 00:14:04.470 and get an estimate of the misclassification rates, right?

295 00:14:04.470 --> 00:14:05.917 Like you can say like,

296 00:14:05.917 --> 00:14:08.370 "Oh okay, so there are 10 cases

 $297\ 00:14:08.370 \longrightarrow 00:14:10.830$  that the MITS cause of death was HIV,

 $298\ 00:14:10.830 \longrightarrow 00:14:12.180$  out of those 10 cases,

299 00:14:12.180  $\rightarrow$  00:14:15.060 seven of them were correctly assigned to HIV

300 00:14:15.060 --> 00:14:16.380 by verbal autopsy.

 $301\ 00:14:16.380 \longrightarrow 00:14:19.980$  So then the sensitivity would be 70%

 $302\ 00:14:19.980 \longrightarrow 00:14:22.827$  and the false positive would be 30%, so on."

303 00:14:27.060 --> 00:14:29.130 So this is the broad idea of the methodology. 304 00:14:29.130 --> 00:14:32.250 So for the COMSA data, which is the unpaired data,

 $305\ 00:14:32.250 \longrightarrow 00:14:34.440$  you get only the verbal autopsy record

306 00:14:34.440 --> 00:14:37.110 so you can get an estimate of the predicted cause of deaths

 $307\ 00:14:37.110 \longrightarrow 00:14:38.880$  from the verbal autopsy.

30800:14:38.880 --> 00:14:41.190 From the CHAMPS data, which is the paired data,

 $309\;00{:}14{:}41{.}190 {\:-\!\!\!-\!\!>} 00{:}14{:}44{.}400$  you can get an estimate of the misclassification rates.

310 00:14:44.400 --> 00:14:47.670 And then the only unknown is then the probabilities

311 00:14:47.670 --> 00:14:49.500 of the cause of death

312 00:14:49.500 --> 00:14:54.090 if you were able to do the MITS autopsy for every death.

313 00:14:54.090 --> 00:14:57.859 So then this is an equation with two knowns and one unknown

 $314\ 00{:}14{:}57.859$  --> 00:15:01.320 and you can solve for it and get the calibrating message.

315 00:15:01.320 --> 00:15:04.533 So that's the broad idea and we do it in a model-based way.

316 00:15:08.880 --> 00:15:10.650 So here's the formal model.

317 00:15:10.650 --> 00:15:14.700 So for the CHAMPS dataset with the unlabeled data or the U,

 $318\ 00:15:14.700 \longrightarrow 00:15:17.280$  we have the predicted labels, ar,

 $319\ 00:15:17.280 \longrightarrow 00:15:18.483$  and then for the,

320 00:15:19.560 --> 00:15:21.000 that's for the COMSA data,

321 00:15:21.000 --> 00:15:22.110 and for the CHAMPS data,

322 00:15:22.110 --> 00:15:25.560 we have both the predicted labels from verbal autopsy, ar,

 $323\ 00{:}15{:}25{.}560 \dashrightarrow 00{:}15{:}27{.}783$  as well as the MITS determine labels, yr.

324 00:15:28.800 --> 00:15:33.120 And our quantity of interest is the probabilities of yr

 $325\ 00:15:34.284 \longrightarrow 00:15:35.984$  belonging to the different causes.

 $326\ 00:15:40.740 \longrightarrow 00:15:43.110$  There's a conditional sign missing here.

 $327\ 00:15:44.250 \longrightarrow 00:15:47.730$  But if the conditional probabilities

328 00:15:47.730 --> 00:15:52.380 are denoted by Mij, which is if the MITS cause is i,

329 00:15:52.380 --> 00:15:55.563 what is the probability that the via predicted cause is j?

330 00:15:57.090 --> 00:15:59.340 Then you can use a law of total probability

331 00:15:59.340  $\rightarrow$  00:16:01.650 to write down the marginal distribution

 $332\ 00:16:01.650 \longrightarrow 00:16:03.270$  of the via predicted cause.

333 00:16:03.270 --> 00:16:06.720 So that would be in terms of the misclassification rates

334 00:16:06.720 --> 00:16:09.680 and the marginal cause distribution of the MITS-COD.

 $335\ 00:16:09.680 \longrightarrow 00:16:11.010$  So that's the whole idea.

336 00:16:11.010 --> 00:16:14.880 So you can write this in terms of a matrix vector notation

337 00:16:14.880 --> 00:16:18.030 as probability of a as M transpose p

338 00:16:18.030 --> 00:16:20.760 where M is the misclassification rate matrix,

 $339\ 00:16:20.760 \longrightarrow 00:16:23.640$  p is the unknown quantity of interest,

 $340\ 00:16:23.640 \longrightarrow 00:16:26.610$  which is probability that the cause of death

341 00:16:26.610 --> 00:16:29.390 is coming from an unknown cause.

 $342\ 00:16:31.440 \longrightarrow 00:16:33.840$  So the data model is very simple,

 $343\ 00:16:33.840 \longrightarrow 00:16:36.000$  but the unlabeled data,

 $344\ 00:16:36.000 \rightarrow 00:16:38.220$  it follows multinomial with this probability

345 00:16:38.220 --> 00:16:41.400 which is coming from this law of total probability.

 $346\ 00:16:41.400 \longrightarrow 00:16:42.690$  And then for the label data,

 $347\ 00:16:42.690 \longrightarrow 00:16:46.320$  this is ar given yr equals to i,

 $348\ 00:16:46.320 \longrightarrow 00:16:47.850$  it follows multinomial with the i

349 00:16:47.850 --> 00:16:49.410 throughout the misclassification matrix.

350 00:16:49.410 --> 00:16:51.030 So if the MITS-COD is i,

 $351\ 00:16:51.030 \longrightarrow 00:16:53.010$  the misclassification rates are given by the i

 $352\ 00:16:53.010 \longrightarrow 00:16:55.350$  throughout the misclassification matrix,

 $353\ 00:16:55.350 \longrightarrow 00:16:58.500$  so it's multinomial with that probability.

 $354\ 00:16:58.500 \longrightarrow 00:17:00.477$  And then we've put priors on M and p

355 00:17:01.349 --> 00:17:03.930 and then we can get estimates of both M and p.

356 00:17:03.930 --> 00:17:06.830 M is a nuisance parameter, p is the parameter of interest.

357 00:17:09.900 --> 00:17:13.380 Just to carefully go over what are the assumptions here.

358 00:17:13.380 --> 00:17:17.610 The main assumption is that the misclassification rates

359 00:17:17.610 --> 00:17:20.040 of verbal autopsy given MITS

 $360\ 00:17:20.040 \longrightarrow 00:17:22.530$  are the same in your label data

 $361\ 00:17:22.530 \longrightarrow 00:17:24.750$  as they would be in your unlabeled data.

 $362\ 00:17:24.750 \longrightarrow 00:17:27.540$  This is not verifiable because we don't have

 $363\ 00:17:27.540 \longrightarrow 00:17:29.760$  any true cause of death in the unlabeled data,

 $364\ 00:17:29.760 \longrightarrow 00:17:30.873$  so it's an assumption.

 $365\ 00:17:33.210 \longrightarrow 00:17:34.890$  Given that the verbal autopsy

 $366\ 00:17:34.890 \longrightarrow 00:17:36.930$  is a function of your symptoms,

367 00:17:36.930 --> 00:17:41.133 the assumption is essentially that given a true cause,

368 00:17:42.000 --> 00:17:44.370 the probability of the symptoms are going to be same

369 00:17:44.370 --> 00:17:46.403 in your unlabeled dataset as in your labeled dataset.

370 00:17:49.207 --> 00:17:50.100 And it's a reasonable assumption

371 00:17:50.100 --> 00:17:52.530 as if you have a cause of death,

372 00:17:52.530 --> 00:17:56.430 it's likely that you have certain symptoms will appear

 $373\ 00:17:56.430 \longrightarrow 00:17:58.500$  and some certain symptoms will not appear.

374 00:17:58.500 --> 00:18:02.400 And that is true regardless of whether the data is coming

 $375\ 00:18:02.400 \longrightarrow 00:18:03.473$  from the labeled set or the unlabeled set.

376 00:18:08.462 --> 00:18:12.240 We do not assume that the marginal distribution

377 00:18:12.240 --> 00:18:15.690 of the CHAMPS data of the causes in the label data

 $378\ 00:18:15.690 \longrightarrow 00:18:17.370$  is representative of the population

379 00:18:17.370 --> 00:18:19.920 because they are not, because the CHAMPS state,

380 00:18:19.920 --> 00:18:21.450 so the CHAMPS project is done

 $381\ 00:18:21.450 \longrightarrow 00:18:24.420$  at specific hospitals in the country

382 00:18:24.420 --> 00:18:27.540 and distribution of causes in hospitals

383 00:18:27.540 --> 00:18:29.910 are typically not same as distribution

 $384\ 00:18:29.910 \longrightarrow 00:18:31.110$  of causes in the community.

 $385\ 00:18:31.110 \longrightarrow 00:18:31.950$  And we are interested

 $386\ 00:18:31.950 \rightarrow 00:18:34.080$  in the cause distribution in the population.

387 00:18:34.080 --> 00:18:35.470 So there is no assumption

388 00:18:36.509 --> 00:18:40.170 that the marginal distribution of y in the label data

389 00:18:40.170 --> 00:18:42.960 is same as the marginal distribution of y in unlabeled data,

 $390\ 00:18:42.960 \longrightarrow 00:18:44.970$  which is our quantity of interest.

 $391\ 00:18:44.970 \longrightarrow 00:18:47.010$  And the reason there is no assumption

 $392\ 00{:}18{:}47.010$  -->  $00{:}18{:}50.610$  is we only model a given y in the label data.

393 00:18:50.610 --> 00:18:53.013 We never model y in the label data.

 $394\ 00:18:53.910 \longrightarrow 00:18:55.560$  So we only model the conditional

395 $00{:}18{:}55{.}560 \dashrightarrow 00{:}18{:}56{.}910$  and the assumption is the condition

 $396\ 00:18:56.910 \longrightarrow 00:18:59.610$  of misclassification rates are transportable

 $397\ 00:18:59.610 \longrightarrow 00:19:01.883$  from the labeled to the unlabeled side.

 $398\ 00:19:05.707 \longrightarrow 00:19:07.230$  So that's the main idea.

 $399\ 00:19:07.230 \longrightarrow 00:19:09.380$  And this was the first work we did,

 $400\ 00:19:09.380 \longrightarrow 00:19:13.170$  we just used this top cause prediction.

401 00:19:13.170 --> 00:19:14.610 But many of these algorithms

 $402\ 00:19:14.610 \longrightarrow 00:19:16.800$  are actually probabilistic in nature in the sense

 $403\ 00:19:16.800 \longrightarrow 00:19:18.090$  that if you look at their outputs,

 $404\ 00:19:18.090 \longrightarrow 00:19:20.130$  they won't give a single cause of death,

 $405\ 00:19:20.130 \longrightarrow 00:19:22.470$  but they will give scores to each cause.

 $406\ 00:19:22.470 \longrightarrow 00:19:23.910$  So for example,

 $407\ 00:19:23.910 \longrightarrow 00:19:26.460$  this would be a typical output of an algorithm  $408\ 00:19:26.460 \longrightarrow 00:19:28.380$  for like say 6%.

 $409\ 00:19:28.380 \longrightarrow 00:19:30.180$  So for the first person, it will say

410 00:19:33.194 --> 00:19:35.344 70% HIV, 20% malaria, 10% sepsis and so on.

411 00:19:38.100 --> 00:19:40.770 And the standard procedure is to take the top cause,

 $412\ 00:19:40.770 \longrightarrow 00:19:43.680$  so for the first person, it would be HIV,

413 00:19:43.680 --> 00:19:47.610 for the second person, it will be malaria and so on.

 $414\ 00:19:47.610 \longrightarrow 00:19:49.590$  So that's how you get a single cause

415 00:19:49.590 --> 00:19:51.190 from a probabilistic prediction.

416  $00:19:53.430 \rightarrow 00:19:56.037$  So that essentially ignores sort of the scores

 $417\ 00:19:57.390 \longrightarrow 00:20:00.810$  assigned to the second most likely cause,

 $418\ 00:20:00.810 \longrightarrow 00:20:03.630$  the third most likely cause and so on.

419 00:20:03.630 --> 00:20:08.630 And you ignore those, you can end up with a biased estimate.

 $420\ 00:20:09.030 \longrightarrow 00:20:11.940$  So you can see these are the CSMF estimates

 $421\ 00:20:11.940 \longrightarrow 00:20:13.650$  using the top cause,

422 00:20:13.650 --> 00:20:14.940 these are the CSM estimates

 $423\ 00:20:14.940 \longrightarrow 00:20:16.950$  using the exact scores that are assigned

424 00:20:16.950 --> 00:20:18.300 and those are different, right?

425 00:20:18.300 --> 00:20:21.600 So when we kind of change this probabilistic output

 $426\ 00{:}20{:}21.600$  -->  $00{:}20{:}25.863$  to a single cause output, we discard information.

 $427\ 00:20:29.640 \longrightarrow 00:20:31.530$  So we wanted to extend the work

428 00:20:31.530 --> 00:20:35.790 to kind of use the full set of scores and the set of scores

429 00:20:35.790 --> 00:20:38.100 can be thought of as a compositional data in the sense

 $430\ 00:20:38.100 \longrightarrow 00:20:40.170$  that the scores sum up to one

431 00:20:40.170 --> 00:20:44.610 because it assigns 100% probability across all causes

 $432\ 00:20:44.610 \longrightarrow 00:20:47.670$  and then they're each non-negative.

433 00:20:47.670  $\rightarrow$  00:20:50.610 The issue is that for the categorical data,

434 00:20:50.610 --> 00:20:53.460 our model is based on multinomial distribution.

 $435\ 00:20:53.460 \longrightarrow 00:20:55.110$  And then for compositional data,

436 $00{:}20{:}55{.}110 \dashrightarrow 00{:}20{:}57{.}030$  the models are typically like Dirichlet

 $437\ 00:20:57.030 \longrightarrow 00:20:58.920$  or log ratio based models,

438 00:20:58.920 --> 00:21:01.870 which are very different from the multinomial distribution.

 $439\ 00:21:03.450 \longrightarrow 00:21:05.070$  So if we have some cases

440 00:21:05.070 - 00:21:07.050 for which we have categorical output,

441 00:21:07.050 --> 00:21:09.090 for some, we have compositional output,

 $442\ 00:21:09.090 \longrightarrow 00:21:10.830$  this would lead to different models

 $443\ 00:21:10.830 \longrightarrow 00:21:12.580$  for different parts of the dataset.

444 00:21:14.760 --> 00:21:16.710 These Dirichlet or log-ratio models

445 00:21:16.710 --> 00:21:19.500 also do not allow zeros in the data.

446 00:21:19.500 --> 00:21:21.810 So if you have zeros or ones in the composition,

 $447\ 00:21:21.810 \longrightarrow 00:21:23.430$  they don't allow that.

448 00:21:23.430 --> 00:21:26.820 And then there are very specific models about the data

449  $00:21:26.820 \rightarrow 00:21:29.100$  which are subjective model and specification.

450 00:21:29.100 --> 00:21:32.670 So the data distribution does not look like a Dirichlet

 $451\ 00:21:32.670 \longrightarrow 00:21:33.660$  assuming a Dirichlet layer

452 00:21:33.660 --> 00:21:37.713 would lead to kind of wrong results.

453 00:21:40.800 --> 00:21:45.800 So how do we extend the multinomial framework we had

454 00:21:46.110  $\rightarrow$  00:21:49.233 for categorical data to compositional data?

 $455\ 00:21:50.790 \longrightarrow 00:21:55.680$  Again, there would be a conditional sign here.

 $456\ 00:21:55.680 \longrightarrow 00:21:57.750$  But the basic assumption that we had

457 00:21:57.750 --> 00:22:01.650 for the multinomial case was probability of a given y

458 00:22:01.650 --> 00:22:04.620 is the i throughout misclassification matrix, right?

459 00:22:04.620 --> 00:22:09.620 And for categorical data, a probability statement

460 00:22:09.900 --> 00:22:12.030 is same as an expectation statement, right?

 $461\ 00:22:12.030 \longrightarrow 00:22:13.860$  So we can equivalently write this

 $462\ 00:22:13.860 \longrightarrow 00:22:16.170$  as expectation of a given y

 $463\ 00:22:16.170 \longrightarrow 00:22:17.470$  is the i throughout the M.

464 00:22:18.919 --> 00:22:20.430 The advantage of the expectation statement

465 00:22:20.430 --> 00:22:23.310 is that it's more generally applicable.

466 00:22:23.310  $\rightarrow 00:22:27.150$  It will not be just for categorical data, right?

467 00:22:27.150 --> 00:22:30.150 So for categorical data, there's a equivalent.

468 00:22:30.150 --> 00:22:33.390 For other data types, this statement can be valid

469 00:22:33.390 --> 00:22:36.690 even though the previous statement may not be applicable.

470 00:22:36.690 --> 00:22:40.887 So we kind of write this as our model

471 00:22:40.887 --> 00:22:45.210 for the compositional data and we make no other assumptions

472 00:22:45.210 --> 00:22:46.260 about this distribution.

 $473\ 00:22:46.260$  --> 00:22:50.920 So only a first moment conditional expectation statement

 $474\ 00:22:53.400 \longrightarrow 00:22:56.313$  without any full distributional specification.

475 00:22:58.650 --> 00:23:00.450 So what do we do?

 $476\ 00:23:00.450 \longrightarrow 00:23:02.880$  So we have expectation of a given y

477 00:23:02.880 --> 00:23:05.343 is the i throughout the misclassification matrix.

 $478\ 00:23:08.040 \longrightarrow 00:23:09.567$  We can use something called

479 00:23:09.567 --> 00:23:11.520 the Kullback Leibler Divergence

 $480\ 00:23:11.520 \longrightarrow 00:23:13.710$  or the cross entropy loss

 $481\ 00:23:13.710 \longrightarrow 00:23:16.770$  between a and its model expectation.

 $482\ 00{:}23{:}16.770$  -->  $00{:}23{:}20.013$  So these are all the conditional signs are missing here.

 $483\ 00:23:22.050 \longrightarrow 00:23:25.353$  So basically a is the data we observe,

 $484\ 00:23:26.400 \longrightarrow 00:23:28.860$  this is the modeled expectation,

 $485\ 00:23:28.860 \longrightarrow 00:23:29.693$  which is basically the i

486 00:23:29.693  $\rightarrow 00:23:31.287$  through of the misclassification matrix

 $487\ 00:23:31.287 \longrightarrow 00:23:33.630$  and we use the cross entropy loss,

 $488\ 00:23:33.630 -> 00:23:36.810$  the Kullback Leibler loss between the two.

 $489\ 00:23:36.810 \longrightarrow 00:23:37.800$  What's the advantage?

490 00:23:37.800 --> 00:23:38.633 So first of all,

491 00:23:38.633 --> 00:23:41.610 the Kullback Leibler loss allows zeroes in the composition.

 $492~00{:}23{:}41.610 \dashrightarrow 00{:}23{:}45.330$  So it is well-defined even if you have zeroes or ones.

493 00:23:45.330 --> 00:23:47.970 If you take the negative loss and exponentiate it,

 $494\ 00:23:47.970 \longrightarrow 00:23:49.940$  it's exactly the multinomial likelihood.

495 00:23:49.940 --> 00:23:52.050 So if your data is indeed multinomial,

496 00:23:52.050 --> 00:23:54.420 you get back your likelihood that you're using

497 00:23:54.420 --> 00:23:57.120 for your single class model.

498 00:23:57.120 --> 00:23:59.550 But if your data is not multinomial,

499 00:23:59.550 --> 00:24:02.100 you get a pseudo likelihood that you can work with.

 $500~00{:}24{:}03{.}960$  -->  $00{:}24{:}06{.}660$  If you can take the derivative of the loss function

501 00:24:06.660 --> 00:24:10.170 and take the expectation under the two parameter,

 $502\ 00:24:10.170 \longrightarrow 00:24:13.001$  you'll see that it's a valid score function

503 00:24:13.001 --> 00:24:15.750 in the sense that you get an unbiased estimating equation

504 00:24:15.750 --> 00:24:18.900 for your misclassification rate matrix, M,

50500:24:18.900 --> 00:24:21.033 based on just the first moment as option.

 $506\;00{:}24{:}22.890 \dashrightarrow 00{:}24{:}24.720$  And then similarly, you can do the same thing

 $507\ 00:24:24.720 \longrightarrow 00:24:26.730$  for the unlabeled data.

508 00:24:26.730 --> 00:24:29.520 The probability statement becomes expectation statement

50900:24:29.520 --> 00:24:32.400 and then we have the Kullback Leibler loss.

510 00:24:32.400 --> 00:24:36.360 This is an unbiased estimated equation for both M and p.

511 00:24:36.360 --> 00:24:37.500 And again,

 $512\ 00{:}24{:}37{.}500$  -->  $00{:}24{:}40{.}680$  if the data is truly multinomial and not compositional,

513 00:24:40.680 --> 00:24:43.410 this becomes exactly the multinomial likelihood.

514 00:24:43.410 --> 00:24:44.760 If the data is compositional,

 $515\ 00:24:44.760 \longrightarrow 00:24:46.310$  it becomes a pseudo likelihood.

516 00:24:49.860 --> 00:24:52.170 Okay, so how do we do Bayes analysis

 $517\ 00:24:52.170 \longrightarrow 00:24:54.240$  with pseudo likelihoods?

 $518\ 00:24:54.240 \longrightarrow 00:24:56.970$  So this is where this idea of generalized Bayes

519 00:24:56.970 --> 00:24:58.920 or model-free Bayesian inference comes in

 $520\ 00:24:58.920 \longrightarrow 00:25:01.200$  and there have been parallel developments

521 00:25:01.200 --> 00:25:04.290 in both computer science, econometrics and statistics

 $522\ 00{:}25{:}04{.}290 \dashrightarrow > 00{:}25{:}06{.}870$  without much communication among the three fields

 $523\ 00:25:06.870 \longrightarrow 00:25:10.080$  for the last 30, 40 years.

524 00:25:10.080 --> 00:25:12.570 Basically, if you're given a loss function

525 00:25:12.570 --> 00:25:15.480 without a given like a full likelihood for the data,

526 00:25:15.480  $\rightarrow 00:25:18.330$  you can take negative of that loss function

 $527\ 00:25:18.330 \longrightarrow 00:25:20.823$  multiplied by some tuning parameter, alpha,

528 00:25:21.870 --> 00:25:25.620 exponentiate it and treat it as a pseudo likelihood

529 00:25:25.620 --> 00:25:27.270 and apply your priors

530 00:25:27.270 --> 00:25:30.000 and then your posterior is going to be proportional to this

531 00:25:30.000  $\rightarrow 00:25:32.850$  as long as the normalization constant exists.

532 00:25:32.850 --> 00:25:35.460 And there has been a lot of work that has shown

 $533\ 00:25:35.460 \longrightarrow 00:25:37.590$  that this is a valid posterior,

 $534\ 00:25:37.590 \longrightarrow 00:25:40.500$  it is a generalization of the Bayesian posterior,

 $535\ 00:25:40.500 \longrightarrow 00:25:42.360$  like if this is an actual likelihood,

 $536\ 00:25:42.360 \longrightarrow 00:25:44.040$  this is the Bayesian posterior,

537 00:25:44.040 --> 00:25:46.173 but if it's not a actual likelihood,

 $538\ 00:25:47.654 \longrightarrow 00:25:49.470$  this has been shown that it basically minimizes

 $539\ 00:25:49.470 \longrightarrow 00:25:52.503$  the Bayes risk for that loss function.

 $540\ 00:25:54.120 \longrightarrow 00:25:56.280$  It has nice asymptotic properties

541 00:25:56.280 --> 00:25:59.400 shown by Victor Chernozhukov in this paper

 $542\ 00:25:59.400 \longrightarrow 00:26:03.960$  and then in this JSS paper in 2016 I think

543 00:26:03.960 --> 00:26:06.000 it showed that if you're given a loss function

544 00:26:06.000 --> 00:26:07.140 and a prior,

545 00:26:07.140 --> 00:26:10.173 this is the only coherent way you can get a posterior.

546 00:26:11.670 --> 00:26:14.670 So there's now been a lot of work and it's been called

547 00:26:14.670 --> 00:26:17.340 by different names like Gibbs posteriors,

548 00:26:17.340 --> 00:26:19.740 pseudo posterior, Laplace-type estimators

549 00:26:19.740 --> 00:26:23.043 and quasi-Bayesian estimators along with generalized Bayes.

 $550\ 00:26:25.470 \longrightarrow 00:26:28.470$  So for our case, we have the pseudo likelihood

 $551\ 00:26:28.470 \longrightarrow 00:26:29.460$  for the label data.

 $552\ 00{:}26{:}29{.}460$  -->  $00{:}26{:}31{.}530$  We have the pseudo likelihood for the unlabeled data.

 $553\ 00:26:31.530 \longrightarrow 00:26:33.270$  We put priors.

554 00:26:33.270 --> 00:26:35.190 If all of our data were categorical,

555 00:26:35.190 --> 00:26:37.560 this reduces to that multinomial model we had

 $556\ 00:26:37.560 \longrightarrow 00:26:39.120$  for the categorical data.

557 00:26:39.120  $\rightarrow$  00:26:41.190 But if some of the data is compositional,

 $558\ 00:26:41.190 \longrightarrow 00:26:43.830$  then this becomes generalized Bayes,

559 00:26:43.830 --> 00:26:47.160 so we call it generalized Bayes quantification learning.

560 00:26:47.160 --> 00:26:50.190 It allows sparsity of the outputs in the sense 561 00:26:50.190 --> 00:26:53.520 that if some of the data have zeroes and ones in them,

 $562\ 00:26:53.520 \longrightarrow 00:26:55.590$  this is well-defined.

 $563\ 00:26:55.590 \longrightarrow 00:26:57.750$  It's the same pseudo likelihood

 $564\ 00:26:57.750 \longrightarrow 00:27:00.510$  for categorical compositional predictions.

 $565\ 00:27:00.510 \longrightarrow 00:27:01.950$  And then it also allows

 $566\ 00:27:01.950 \longrightarrow 00:27:05.013$  a nice Gibbs sample using conjugacy.

 $567\ 00:27:10.920 \longrightarrow 00:27:14.820$  One final sort of data aspect we had

 $568\ 00:27:14.820 \longrightarrow 00:27:18.420$  was that this minimal tissue sampling

569 00:27:18.420 --> 00:27:20.730 was also sometimes inconclusive in the sense

 $570\ 00:27:20.730 \longrightarrow 00:27:22.230$  that they gave two causes.

571 00:27:22.230 --> 00:27:27.230 Like often, they were ambiguous between HIV and tuberculosis

572 00:27:28.890 --> 00:27:30.750 and they would give one as the immediate cause

 $573\ 00:27:30.750 \longrightarrow 00:27:32.040$  and one as the underlying cause.

574 00:27:32.040 --> 00:27:35.820 So sometimes, even the true cause of death is compositional.

575 00:27:35.820 --> 00:27:38.790 So your predicted cause of death is compositional,

576 00:27:38.790 --> 00:27:40.647 your true cause of death is also compositional 577 00:27:40.647 --> 00:27:45.270 and we call it like b, which represents the belief.

 $578\ 00:27:45.270 \longrightarrow 00:27:49.380$  And you can show that if you're only given b  $579\ 00:27:49.380 \longrightarrow 00:27:51.273$  instead of a single cause of death,

580 00:27:52.603 --> 00:27:55.800 your conditional expectation becomes M transpose b

 $581\ 00:27:55.800 \longrightarrow 00:27:59.340$  instead of the i through of the M matrix.

 $582\ 00:27:59.340 \longrightarrow 00:28:01.380$  And you can do the same thing

 $583\ 00:28:01.380 \rightarrow 00:28:04.543$  using the compositional true cause of death

 $584~00{:}28{:}04.543 \dashrightarrow 00{:}28{:}07.620$  instead of the actual true cause of death.

585 00:28:07.620 --> 00:28:09.540 And all the conditional signs are missing here

586 00:28:09.540 --> 00:28:13.800 but you can just formulate the Kullback Leibler likelihood

587 00:28:13.800 --> 00:28:16.593 to generate pseudo likelihood.

588 00:28:18.870 --> 00:28:21.570 So this kind of give rise to a digression

 $589\ 00:28:21.570 - 00:28:24.040$  where we kind of looked at this is basically

590 00:28:25.152 --> 00:28:28.080 your true cause of death is a compositional covariate

591 00:28:28.080 --> 00:28:31.350 and your predicted cause of death is a compositional output.

 $592\ 00:28:31.350 \longrightarrow 00:28:33.120$  So we kind of looked at regression

593 00:28:33.120 --> 00:28:36.270 of a compositional outcome on compositional predictors.

594 00:28:36.270 --> 00:28:39.750 So this was kind of an offshoot paper

 $595\ 00:28:39.750 \longrightarrow 00:28:41.850$  where we just developed this piece

 $596\ 00:28:41.850 \longrightarrow 00:28:45.390$  and if you look at compositional regression,

 $597~00{:}28{:}45{.}390 \dashrightarrow > 00{:}28{:}50{.}160$  most of the work has been done using Dirichlet models

 $598\ 00:28:50.160 \longrightarrow 00:28:52.440$  or log ratio transformations.

599 00:28:52.440 --> 00:28:55.343 So this was a different approach to that in the sense

 $600\ 00:28:55.343 \longrightarrow 00:28:57.060$  that it's both transformation free

601 00:28:57.060 --> 00:28:58.920 and it doesn't specify a whole distribution

 $602 \ 00:28:58.920 \longrightarrow 00:28:59.753$  like the Dirichlet,

 $603\ 00:28:59.753 \longrightarrow 00:29:02.040$  it just uses a first moment as option.

60400:29:02.040 --> 00:29:07.040 And we have an R-package to do a regression on composition,

60500:29:07.470 --> 00:29:10.370 to do composition on composition regression called codalm.

606 00:29:12.150 --> 00:29:14.673 But going back to the verbal autopsy work,

 $607\ 00:29:16.050 \longrightarrow 00:29:17.220$  we have the loss functions

 $608\ 00:29:17.220 \longrightarrow 00:29:19.173$  for the labeled and unlabeled data,

 $609\ 00:29:20.220 \longrightarrow 00:29:22.500$  we do the negative pseudo likelihoods,

 $610\ 00{:}29{:}22.500$  -->  $00{:}29{:}26.103$  put priors on the parameters and we get posterior inference.

611 00:29:27.780 --> 00:29:30.990 One last extension of the methodology

 $612\ 00:29:30.990 \longrightarrow 00:29:33.780$  was that there are multiple different

613 00:29:33.780 --> 00:29:35.970 verbal autopsy algorithms and there are papers

614 00:29:35.970 --> 00:29:38.700 where every new algorithm comes out and they say

 $615\ 00:29:38.700$  --> 00:29:40.620 they're better than all the previous algorithms.

61600:29:40.620 $\operatorname{-->}$ 00:29:44.190 And in practice, you never know which is the best algorithm.

617 00:29:44.190 --> 00:29:48.990 So we developed an ensemble method that takes in predictions

618 00:29:48.990 --> 00:29:53.760 from multiple algorithms, estimates classifier

 $619\ 00:29:53.760 \longrightarrow 00:29:56.550$  algorithm-specific misclassification rates

 $620\ 00{:}29{:}56{.}550$  -->  $00{:}30{:}00{.}270$  and then they're connected to the unknown estimand.

 $621\ 00:30:00.270 \longrightarrow 00:30:04.140$  So we can show that it gives more weight

 $622\ 00{:}30{:}04.140$  -->  $00{:}30{:}06.900$  to the more accurate algorithm in a data-driven way.

623 00:30:06.900 --> 00:30:10.380 And then you're not kind of,

 $624\ 00:30:10.380 \longrightarrow 00:30:11.970$  you don't have to make the choice

 $625\ 00{:}30{:}11.970 \dashrightarrow 00{:}30{:}13.950$  of which is the best algorithm in advance.

626 00:30:13.950 --> 00:30:15.300 If you have multiple candidates,

 $627\ 00:30:15.300 \longrightarrow 00:30:18.603$  you can use multiple algorithms together.

62800:30:22.560 --> 00:30:26.340 So we looked at some theoretical properties of the method.

629 00:30:26.340 --> 00:30:28.830 We have two log functions, one for the label data,

 $630\ 00:30:28.830 \longrightarrow 00:30:31.080$  one for the unlabeled data.

631 00:30:31.080 --> 00:30:31.913 The label data

632 00:30:31.913 --> 00:30:35.610 doesn't even feature the estimand, which is p,

633 00:30:35.610 --> 00:30:38.910 so it will, on its own, it cannot identify p.

63400:30:38.910 --> 00:30:43.050 The unlabeled data only uses p through this quantity,

635 00:30:43.050 --> 00:30:44.190 M transpose p.

636 00:30:44.190 --> 00:30:47.640 So again, for different combinations of M and p,

 $637\ 00:30:47.640 \longrightarrow 00:30:49.800$  as long as this product is the same,

 $638\ 00:30:49.800 \longrightarrow 00:30:52.680$  it will never be able to identify p on its own.

639 00:30:52.680 --> 00:30:54.240 So each loss function on its own

 $640\ 00:30:54.240 \longrightarrow 00:30:56.520$  cannot identify through parameters.

641 00:30:56.520 --> 00:30:59.070 But using both the loss functions together,

 $642\ 00:30:59.070 \longrightarrow 00:31:02.070$  you can identify the estimand, T,

643 00:31:02.070 --> 00:31:06.360 and we were able to show that posterior has nice properties

644 00:31:06.360 --> 00:31:08.400 in terms of asymptotic normality

645 00:31:08.400 --> 00:31:10.500 and well calibrated interval estimate

 $646\ 00:31:10.500 \longrightarrow 00:31:12.990$  and near parametric concentration rates.

647 00:31:12.990 --> 00:31:16.320 And the theory also extends to the ensemble method

648 00:31:16.320 --> 00:31:19.470 and we use some approximations and we give sampler

 $649\ 00:31:19.470 \longrightarrow 00:31:21.273$  and theory holds for that.

 $650\ 00:31:24.150 \longrightarrow 00:31:25.953$  Some empirical validations,

651 00:31:27.450 --> 00:31:32.220 since we're estimating a probability vector,

 $652\ 00:31:32.220 \longrightarrow 00:31:34.380$  the common metric that is used is called

653 00:31:34.380 --> 00:31:37.800 this chance-corrected normalized absolute accuracy,

 $654\ 00:31:37.800 \longrightarrow 00:31:40.743$  which is basically a scaled L1 error,

655 00:31:41.670 --> 00:31:45.510 centered by the L1 error you would get if you had predicted

 $656\ 00:31:45.510 \longrightarrow 00:31:46.740$  the cause of death randomly.

 $657\ 00:31:46.740 \rightarrow 00:31:49.500$  So this is the error if you predict randomly

658 00:31:49.500 --> 00:31:51.900 and then we look at how much improvement we get

 $659\ 00:31:51.900 \longrightarrow 00:31:53.613$  over random predictions.

66000:31:56.790 --> 00:32:00.510 So this is an illustration of what happens if the data

661 00:32:00.510 --> 00:32:03.420 is not Dirichlet and you use Dirichlet distribution.

 $662\ 00:32:03.420 \longrightarrow 00:32:05.070$  So on the left-hand side,

 $663\ 00:32:05.070 \longrightarrow 00:32:07.647$  the data is generated from Dirichlet

 $664~00{:}32{:}07.647 \dashrightarrow 00{:}32{:}11.880$  and we use both our method and the Dirichlet-based model

 $665\ 00:32:11.880 \longrightarrow 00:32:13.650$  and they both do well.

 $666\ 00:32:13.650 \longrightarrow 00:32:14.670$  On the right-hand side,

667 00:32:14.670 --> 00:32:17.490 the data is from an overdispersed Dirichlet

 $668\ 00:32:17.490 \longrightarrow 00:32:19.530$  and we use the Dirichlet in our model.

669 00:32:19.530 --> 00:32:22.080 And because our model doesn't specify a distribution,

670 00:32:22.080 --> 00:32:24.690 it just uses a first moment specification,

 $671\ 00:32:24.690$  --> 00:32:27.820 it's much robust and has much higher accuracy  $672\ 00:32:28.860$  --> 00:32:31.657 than for the Dirichlet which becomes misspecified.

673 00:32:35.010 --> 00:32:37.020 And then we also did a bunch of evaluations 674 00:32:37.020 --> 00:32:38.400 using the PHMRC data.

 $675\ 00:32:38.400 \longrightarrow 00:32:41.580$  So what we did was we trained the classifiers  $676\ 00:32:41.580 \longrightarrow 00:32:44.370$  on three of the countries leaving one country out

677 00:32:44.370 --> 00:32:47.460 and then used a slice of data from that left out country

 $678\ 00:32:47.460 \longrightarrow 00:32:49.710$  to estimate the misclassification rates,

 $679\ 00:32:49.710 \longrightarrow 00:32:51.723$  and then we apply our method.

 $680\ 00:32:54.600 \longrightarrow 00:32:56.400$  The green one is our method

 $681\ 00:32:56.400 \rightarrow 00:33:01.400$  and the x axis is the sample size of the dataset

 $682\ 00:33:02.220 \longrightarrow 00:33:04.154$  used from the left out country

68300:33:04.154 --> 00:33:06.930 to estimate the misclassification rates.

 $684\ 00:33:06.930 \longrightarrow 00:33:10.650$  The blue one is sort of the uncalibrated one,

 $685\ 00:33:10.650 \longrightarrow 00:33:12.750$  the red one is the one that is calibrated

 $686\ 00:33:12.750 \longrightarrow 00:33:14.250$  using the training data.

687 00:33:14.250 --> 00:33:17.760 So you can see that our method does better than both of them

 $688\ 00:33:17.760 \longrightarrow 00:33:20.220$  and the higher the sample size we use

689 00:33:20.220 --> 00:33:22.890 from the left out country of interest

690 00:33:22.890 --> 00:33:25.973 to estimate the misclassifications, the more accurate it is.

691 00:33:29.637 --> 00:33:31.440 And also one interesting aspect

 $692\ 00:33:31.440 \longrightarrow 00:33:33.300$  was that we looked at calibration

693 00:33:33.300 --> 00:33:35.700 using individual algorithms and the calibration

 $694\ 00:33:35.700 \longrightarrow 00:33:37.440$  using the ensemble one.

 $695\ 00:33:37.440 -> 00:33:40.380$  And more often than not, the ensemble one,

 $696\ 00:33:40.380 \longrightarrow 00:33:41.970$  which is the orange one,

 $697~00{:}33{:}41.970$  -->  $00{:}33{:}45.570$  tends to perform similar to the best performing algorithm,

698 00:33:45.570 --> 00:33:48.450 and the best performing algorithm can be very different

 $699\ 00:33:48.450 \longrightarrow 00:33:49.530$  across different countries.

 $700\ 00:33:49.530 \longrightarrow 00:33:51.450$  For example, in Mexico,

 $701\ 00{:}33{:}51.450 \dashrightarrow 00{:}33{:}54.120$  In SilicoVA is one of the best performing algorithms,

702 00:33:54.120 --> 00:33:57.390 but in Tanzania, InSilicoVA was doing very poorly

703 00:33:57.390 --> 00:33:58.660 and then InterVA was one

 $704\ 00:33:59.499 \longrightarrow 00:34:00.332$  of the better performing algorithms.

705 00:34:00.332 --> 00:34:02.970 So the ensemble always tend to give more weights

 $706\ 00:34:02.970 \longrightarrow 00:34:04.773$  to more accurate algorithms.

707 00:34:07.380 --> 00:34:10.020 So this is an overview of what we did for Mozambique.

 $708\ 00{:}34{:}10.020$  -->  $00{:}34{:}13.920$  So we had the unlabeled data with only verbal autopsies.

 $709\ 00:34:13.920 \longrightarrow 00:34:16.230$  We've passed it through two algorithms,

710 00:34:16.230 --> 00:34:20.520 InSilicoVA and Expert VA, to get the uncalibrated estimates.

711 00:34:20.520 --> 00:34:23.070 Then we had the label data with the MITS cause of death

 $712\ 00:34:23.070 \longrightarrow 00:34:25.350$  with which we estimated the misclassifications

 $713\ 00:34:25.350 \longrightarrow 00:34:27.660$  of those two algorithms

714 00:34:27.660 --> 00:34:30.450 and then we combine them in the ensemble method

 $715\ 00:34:30.450 \longrightarrow 00:34:32.100$  and getting calibrated estimates.

716 00:34:37.680 --> 00:34:39.900 Some results from Mozambique.

 $717\ 00:34:39.900 \longrightarrow 00:34:41.520$  We have two age groups,

718 00:34:41.520 --> 00:34:44.850 neonatal deaths, first four weeks,

 $719\ 00:34:44.850 \longrightarrow 00:34:47.820$  and children that's under five years.

720 $00{:}34{:}47.820$  -->  $00{:}34{:}51.720$  Two algorithms, seven causes of death for children,

 $721\ 00:34:51.720 \longrightarrow 00:34:53.613$  five causes of death for neonates.

 $722\ 00{:}34{:}54.690$  -->  $00{:}34{:}56.880$  I'm going to just show the neonatal results here.

 $723\ 00{:}34{:}56{.}880$  -->  $00{:}35{:}00{.}540$  So these are the misclassification matrices for neonates.

 $724\ 00:35:00.540 \longrightarrow 00:35:03.060$  And ideally, you would want the matrices

725 $00{:}35{:}03.060 \dashrightarrow 00{:}35{:}04.890$  to have large numbers on the diagonals

726 00:35:04.890  $\rightarrow 00:35:06.840$  because those are the correct matches

 $727\ 00:35:06.840 \longrightarrow 00:35:08.910$  and then small numbers on the off diagonals.

 $728\ 00:35:08.910 \longrightarrow 00:35:09.930$  But you don't see that,

729 00:35:09.930 --> 00:35:14.040 you see quite a bit of large numbers on the off diagonals.

 $730\ 00:35:14.040 \longrightarrow 00:35:16.740$  One thing that stands out is that

731 00:35:16.740 --> 00:35:20.490 if you look at prematurity, it has a very high sensitivity,

732 00:35:20.490  $\rightarrow 00:35:21.750$  close to 90%,

733 00:35:21.750 --> 00:35:25.110 which means that if the true cause is prematurity,

 $734\ 00:35:25.110 \longrightarrow 00:35:28.050$  the verbal autopsy correctly diagnoses it.

735 00:35:28.050 --> 00:35:30.960 But then it also has high false positives

736  $00:35:30.960 \rightarrow 00:35:34.050$  in the sense that if the true cause is infection,

 $737\ 00:35:34.050 \longrightarrow 00:35:37.020\ 20\%$  of time, it is assigned as prematurity.

 $738\ 00:35:37.020 \longrightarrow 00:35:40.149$  If the true cause is intrapartum related events,

 $739\ 00:35:40.149 \longrightarrow 00:35:40.982$  almost 30% of time,

740  $00:35:40.982 \rightarrow 00:35:43.020$  it's assigned to be prematurity and so on.

741 00:35:43.020 --> 00:35:46.170 So it tends to over count a lot of deaths

 $742\ 00:35:46.170 \longrightarrow 00:35:48.480$  from different causes as prematurity.

743 00:35:48.480  $\rightarrow 00:35:51.540$  So what would be the result after calibration

744 00:35:51.540 --> 00:35:54.240 is that the percentage of prematurity comes down.

745 00:35:54.240 --> 00:35:58.380 So this is the uncalibrated estimate of prematurity.

746  $00:35:58.380 \rightarrow 00:36:00.780$  This is the calibrated estimate of prematurity.

747 00:36:00.780 --> 00:36:02.130 You can see that it comes down

748 00:36:02.130 --> 00:36:04.980 because we can see in the data that there is a lot

749 00:36:04.980 --> 00:36:07.353 of over counting of prematurity deaths.

750 00:36:08.820 --> 00:36:12.093 So after calibration, it tends to come down quite a bit.

751 00:36:16.950 --> 00:36:21.510 And also, we looked at the model estimated sensitivities

 $752\ 00:36:21.510 \longrightarrow 00:36:23.550$  using both the single cause

 $753\ 00:36:23.550 \longrightarrow 00:36:26.043$  and the compositional cause of the data.

 $754\ 00:36:27.180 \longrightarrow 00:36:29.460$  So this is the difference in the sensitivities

755 00:36:29.460 --> 00:36:32.550 and you can see that using the compositional cause of death,

756 00:36:32.550 --> 00:36:36.330 you'll always get a higher match because it kind of uses

757 00:36:36.330  $\rightarrow 00:36:38.580$  information for multiple causes and stuff

758 00:36:38.580 --> 00:36:40.530 just considering the top cause.

 $759\ 00:36:40.530 \longrightarrow 00:36:42.660$  And so it generally leads to better matching

760 00:36:42.660 --> 00:36:46.263 between the verbal autopsy and the minimal tissue sampling.

761 00:36:49.440 --> 00:36:50.730 Some ongoing work.

762 00:36:50.730 --> 00:36:53.010 So when we did this for Mozambique,

763 00:36:53.010  $\rightarrow$  00:36:56.820 there was very little amount of payer data.

764 00:36:56.820 --> 00:36:59.070 So even though the data was for seven countries,

765 00:36:59.070 --> 00:37:00.990 we kind of merged them together

 $766\ 00:37:00.990 \longrightarrow 00:37:03.900$  and estimated the misclassification rates.

767 00:37:03.900 --> 00:37:06.600 Now we have more data coming in for those countries

768 00:37:06.600 --> 00:37:07.920 so we have a chance to assess

769 00:37:07.920 --> 00:37:11.610 whether the misclassification rates vary by country

770 00:37:11.610 --> 00:37:12.450 because if they do,

771 00:37:12.450  $\rightarrow 00:37:14.920$  we should model the misclassification rates

 $772\ 00:37:16.980 \longrightarrow 00:37:19.173$  in a way that's specific to each country.

773 $00{:}37{:}21.420 \dashrightarrow 00{:}37{:}25.890$  So these are the misclassification rates now

 $774\ 00:37:25.890 \longrightarrow 00:37:27.270$  resolved by country.

775 00:37:27.270 --> 00:37:30.030 So there are six countries, Bangladesh, Ethiopia,

776 00:37:30.030 --> 00:37:32.283 Kenya, Mali, Mozambique and Sierra Leone.

777 00:37:34.560 --> 00:37:35.760 You can see the estimates.

 $778\ 00:37:35.760 \longrightarrow 00:37:37.260$  These are the empirical estimates

779  $00:37:37.260 \rightarrow 00:37:40.020$  and the confidence intervals for each country.

780 00:37:40.020 --> 00:37:42.090 And the horizontal black line

 $781\ 00:37:42.090 \longrightarrow 00:37:43.980$  is what the pooled estimate looks like.

782 00:37:43.980 --> 00:37:48.660 So you can see that there is for some causes like here,

783  $00:37:48.660 \rightarrow 00:37:51.240$  there is not a variability across countries.

784 00:37:51.240 --> 00:37:55.353 But then for some other cause payers like say here,

 $785\ 00{:}37{:}56.250$  -->  $00{:}37{:}59.641$  there's quite a bit of variability across countries.

786 00:37:59.641 --> 00:38:03.390 And so now that we are getting more data,

 $787\ 00:38:03.390 \longrightarrow 00:38:05.400$  the next step for the project

 $788\ 00:38:05.400$  --> 00:38:08.790 is to estimate country-specific misclassification rates.

789 00:38:08.790 --> 00:38:12.450 The issue however is that even with more data,

790 00:38:12.450 --> 00:38:16.530 there is, I think, around 600 cases here for six countries,

791 00:38:16.530 --> 00:38:19.560 which is approximately 100 case per country.

792 00:38:19.560 --> 00:38:22.680 And there are 25 cells of the misclassification matrix.

 $793\ 00:38:22.680 \longrightarrow 00:38:24.720$  So that's like four cases per cell,

 $794\ 00:38:24.720 \longrightarrow 00:38:27.450$  so that's clearly not enough to do separate

 $795\ 00:38:27.450 \longrightarrow 00:38:29.670$  country specific models.

796 00:38:29.670 --> 00:38:32.220 So we'd have to kind of do

797 00:38:32.220 --> 00:38:34.950 a sort of a borrowing of information

798 00:38:34.950 --> 00:38:37.920 both across the rows and columns of the matrix

 $799\ 00:38:37.920 \longrightarrow 00:38:40.083$  but also across different countries.

 $800\ 00:38:42.000$  --> 00:38:45.480 So what we do first is first, we kind of borrow information

80100:38:45.480 --> 00:38:48.540 across the rows and columns of the matrix.

 $802\ 00:38:48.540 \longrightarrow 00:38:52.200$  And to do this, we start with a,

803 00:38:52.200 --> 00:38:54.510 instead of an unstructured misclassification matrix

 $804\ 00:38:54.510 \longrightarrow 00:38:56.910$  where we estimated each cell separately,

80500:38:56.910 --> 00:39:00.120 we start with a structured misclassification matrix

 $806\ 00:39:00.120 \longrightarrow 00:39:01.680$  using two basic mechanisms.

 $807\ 00{:}39{:}01.680$  -->  $00{:}39{:}06.680$  So we say that a classifier operates using two mechanisms,

 $808\ 00{:}39{:}07{.}260$  -->  $00{:}39{:}11{.}520$  for a given cause, it can either match that cause

 $809\ 00:39:11.520 \longrightarrow 00:39:14.760$  and we call that an intrinsic accuracy

 $810\ 00:39:14.760 \longrightarrow 00:39:17.550$  and that matching probability will be different

81100:39:17.550 --> 00:39:20.250 for different causes, so there are three causes here,

812 00:39:20.250 --> 00:39:21.330 and you can see

 $813\ 00:39:21.330 \longrightarrow 00:39:23.940$  that the matching probability can be different.

 $814\ 00:39:23.940 \longrightarrow 00:39:25.950$  If it doesn't match the true cause,

 $815 \ 00:39:25.950 \longrightarrow 00:39:28.860$  then it randomly distributes its prediction

816 00:39:28.860 --> 00:39:30.750 to the other causes

817 00:39:30.750 --> 00:39:35.750 and that random distribution will also have some weights,

 $818\ 00:39:35.970 \longrightarrow 00:39:38.190$  and those we call the systematic bias

819 00:39:38.190 --> 00:39:39.570 or the pool of the classifier.

820 00:39:39.570 --> 00:39:41.550 So if it's not matching,

 $821\ 00{:}39{:}41.550$  -->  $00{:}39{:}45.780$  we saw that it'll often assign a cause to prematurity

 $822\ 00:39:45.780 \longrightarrow 00:39:47.730$  regardless of what the true cause is.

 $823\ 00:39:47.730$  --> 00:39:50.550 So that's kind of the basis for this model.

824 00:39:50.550 --> 00:39:51.810 And if you have this model,

 $825\ 00:39:51.810 \longrightarrow 00:39:56.230$  we kind of rearrange these three bars here

 $826\ 00{:}39{:}57{.}420$  -->  $00{:}39{:}59{.}370$  and then we put in the circle from there.

827 00:39:59.370 --> 00:40:03.120 And these will give you the misclassification priorities.

82800:40:03.120 --> 00:40:08.120 So we can write each of the misclassification probabilities

 $829~00{:}40{:}08.340$  -->  $00{:}40{:}12.630$  in terms of just these six parameters and we can do the same

 $830\ 00{:}40{:}12.630$  -->  $00{:}40{:}16.890$  for the green cause and for the blue cause.

831 00:40:16.890 --> 00:40:21.570 And so basically, these are the nine misclassification rates

83200:40:21.570 $\dashrightarrow >$ 00:40:23.300 written in terms of the six parameters.

833 00:40:23.300 --> 00:40:25.680 So this is not that much of a dimension reduction

834 00:40:25.680 --> 00:40:27.300 if there are three causes,

 $835\ 00:40:27.300 \longrightarrow 00:40:30.213$  but if there are in general C causes,

836 00:40:31.710 --> 00:40:34.470 this model for misclassification matrix will only have

837 00:40:34.470 --> 00:40:38.640 2C - 1 parameters as opposed to C square parameters.

838 00:40:38.640 --> 00:40:43.190 So in practice, we use seven causes for children

 $839\ 00:40:43.190 \longrightarrow 00:40:44.023$  and five causes for neonates,

 $840\ 00{:}40{:}44.023$  -->  $00{:}40{:}46.310$  so this leads to a lot of dimension reduction.

841 00:40:48.690 - > 00:40:52.500 And one of the justification

 $842\ 00:40:52.500 \longrightarrow 00:40:54.360$  for this dimension reduced model

843 00:40:54.360 --> 00:40:59.070 is that if this model is true then the misclassification

 $844\ 00:40:59.070 \longrightarrow 00:41:01.380$  into different causes,

845 00:41:01.380 --> 00:41:05.220 the odds of misclassification into two causes, j and k,

 $846\ 00:41:05.220 \longrightarrow 00:41:08.040$  will not depend on what the true cause is.

847 00:41:08.040 --> 00:41:09.720 And we do see that in the data.

848 00:41:09.720 --> 00:41:13.470 So these are different cause payers, j and k,

849 00:41:13.470 --> 00:41:16.920 and these are the odds for what the true cause is.

 $850\ 00:41:16.920 \longrightarrow 00:41:19.890$  So we are plotting the misclassification rates,

851 00:41:19.890 --> 00:41:22.290 mij over mik.

852 00:41:22.290 --> 00:41:23.550 So this is j and k

 $853\ 00:41:23.550 \longrightarrow 00:41:25.680$  and the colors here give you i.

 $854\ 00:41:25.680 \longrightarrow 00:41:28.470$  So you do see that they do not vary

 $855\ 00:41:28.470 \longrightarrow 00:41:30.030$  for different choices of i,

 $856\ 00:41:30.030 \longrightarrow 00:41:32.037$  it only is specific to j and k,

 $857\ 00:41:32.037 \longrightarrow 00:41:35.730$  and that's an equivalent characterization

 $858\ 00:41:35.730 \longrightarrow 00:41:38.970$  of that systematic preference

859 00:41:38.970 --> 00:41:41.070 and intrinsic accuracy model that we have,

 $860\ 00:41:41.070 \longrightarrow 00:41:43.203$  so we do see that reflected in the data.

861 00:41:44.040 --> 00:41:49.040 But we don't have that as the fixed model we have.

862 00:41:49.230 --> 00:41:50.520 So this is the best model.

863 00:41:50.520 --> 00:41:53.997 We allow some diversion or shrinkage towards it

864 00:41:53.997 --> 00:41:55.800 and there's a tuning parameter.

 $865\ 00:41:55.800 \longrightarrow 00:41:58.230$  So then we get the homogeneous model

 $866~00{:}41{:}58.230$  -->  $00{:}42{:}01.260$  and then we have a diversion from the homogeneous model

 $867\ 00:42:01.260 \longrightarrow 00:42:02.730$  to get country specific model.

 $868\ 00:42:02.730 \longrightarrow 00:42:04.380$  So that's the broad idea,

 $869\ 00:42:04.380 \longrightarrow 00:42:06.810$  I won't go into the modeling details.

 $870\ 00:42:06.810 \longrightarrow 00:42:08.760$  And these are the predictions

 $871\ 00:42:08.760 \longrightarrow 00:42:10.563$  using the country specific model.

 $872\ 00{:}42{:}12.750\ -{-}>\ 00{:}42{:}15.270$  I won't go into details here, but there are many cases,

 $873\ 00:42:15.270 \longrightarrow 00:42:16.620$  for example, take it here,

 $874\ 00:42:16.620 \longrightarrow 00:42:18.393$  star is the empirical rate,

 $875\ 00:42:19.440 \longrightarrow 00:42:24.180$  angle is the heterogeneous model.

876 00:42:24.180 --> 00:42:25.650 And you can see it does much better

 $877\ 00{:}42{:}25.650$  -->  $00{:}42{:}29.524$  than the horizontal line, which is the homogeneous model.

87800:42:29.524 --> 00:42:34.163 And we do see it throughout the classification rates.

 $879\ 00:42:35.850 \longrightarrow 00:42:37.620$  These are the estimates for Bangladesh.

880 00:42:37.620  $\rightarrow$  00:42:41.030 So the red density is the pooled estimate

 $881\ 00:42:41.030 \longrightarrow 00:42:42.780$  of the homogeneous estimate.

882 00:42:42.780 --> 00:42:45.543 The blue density is the Bangladesh specific estimate.

883 00:42:48.090 --> 00:42:49.590 The dotted vertical line

 $884\ 00:42:49.590 \longrightarrow 00:42:51.657$  is the empirical estimate for Bangladesh

885 00:42:51.657 --> 00:42:53.430 and the solid vertical line

886 00:42:53.430 --> 00:42:56.250 is the pooled empirical estimate.

887 00:42:56.250 --> 00:42:58.620 So you can see that as we get

888 00:42:58.620 --> 00:43:00.600 more and more data from Bangladesh,

 $889\ 00:43:00.600 \longrightarrow 00:43:02.670$  the country specific estimate moves away

890 00:43:02.670 --> 00:43:03.780 from the pooled estimate

 $891\ 00:43:03.780 \longrightarrow 00:43:06.090$  towards the country specific estimate.

 $892\ 00{:}43{:}06.090$  -->  $00{:}43{:}11.090$  So that's basically the hope is going forward,  $893\ 00{:}43{:}11.790$  -->  $00{:}43{:}14.220$  we will have much more data within each country

89400:43:14.220 $\operatorname{-->}$ 00:43:16.410 and we'll have estimates that are much closer

89500:43:16.410 $\dashrightarrow 00:43:20.013$  to the dotted lines than the solid lines.

 $896\ 00:43:21.810 \longrightarrow 00:43:22.950$  So that's the summary.

 $897\ 00:43:22.950 \longrightarrow 00:43:26.310$  So in general, these cause of death classifiers  $898\ 00:43:26.310 \longrightarrow 00:43:27.810$  are super inaccurate.

89900:43:27.810 --> 00:43:30.840 So we need to calibrate for that and we have limited data

 $900\ 00:43:30.840 \longrightarrow 00:43:32.490$  to estimate their inaccuracy,

 $901\ 00:43:32.490 \longrightarrow 00:43:34.773$  so we calibrate them innovation way.

 $902\;00{:}43{:}36{.}240 \dashrightarrow 00{:}43{:}38{.}790$  The methods give probabilistic cause of death

 $903\ 00:43:38.790 \longrightarrow 00:43:40.350$  instead of categorical cause of death.

 $904\ 00:43:40.350 \longrightarrow 00:43:42.960$  So we develop a generalized Bayes approach

 $905\ 00:43:42.960 \longrightarrow 00:43:45.060$  that is equivalent to a multinomial model

906 00:43:45.060 --> 00:43:47.040 if the data is categorical.

907 00:43:47.040 --> 00:43:50.370 But if it's not categorical, it becomes a pseudo likelihood

908 00:43:50.370  $\rightarrow$  00:43:53.550 Bayesian approach for compositional data

 $909\ 00:43:53.550 -> 00:43:57.000$  and that allows zeroes and ones in the data

910 00:43:57.000 --> 00:44:01.023 and is not kind of dependent on the model specification.

911 00:44:02.490 --> 00:44:04.830 And then it kind of led to this independent development

 $912\ 00:44:04.830 \longrightarrow 00:44:09.020$  of the composition on composition regression.

 $913\ 00:44:09.020 \longrightarrow 00:44:10.216$  Some papers and software.

 $914\ 00:44:10.216 \rightarrow 00:44:13.100$  So the single cause paper was the first one,

915 00:44:13.100 --> 00:44:16.934 then we extend it to compositional data

916 00:44:16.934 --> 00:44:18.991 and develop the theory for it.

917 00:44:18.991 --> 00:44:22.394 The package for calibration is available on GitHub

918 00:44:22.394 --> 00:44:24.720 and then the composition on composition regression

 $919\ 00:44:24.720 \longrightarrow 00:44:25.980$  were the separate piece

 $920\ 00{:}44{:}25{.}980$  -->  $00{:}44{:}30{.}360$  and we have the coda linear model package for it on CRAN.

921 00:44:30.360 --> 00:44:32.460 And then we use this approach

922 00:44:32.460 --> 00:44:34.840 to produce calibration estimates

923 00:44:36.372 --> 00:44:38.970 for neonate and children deaths in Mozambique

 $924\ 00:44:38.970 \longrightarrow 00:44:41.490$  which were published in the last three papers.

925 00:44:41.490 --> 00:44:42.323 Thank you.

926 00:44:51.390 --> 00:44:52.950 <v ->Questions? Yes.</v>

927 00:44:52.950 --> 00:44:54.990 <v ->So I just had a quick question 'cause you were saying</v>

 $928\ 00:44:54.990 \rightarrow 00:44:58.110$  the model basically looks at the symptoms

 $929\ 00:44:58.110 \longrightarrow 00:45:00.000\ \text{that'll be able to predict which it would be.}$ 

930 00:45:00.000 --> 00:45:03.660 Does it also factor in what diseases and stuff

931 00:45:03.660 --> 00:45:07.140 are most common in those areas or does it kind of just-

932 00:45:07.140 --> 00:45:09.360 <v ->Oh, very good question.</v>

 $933\ 00:45:09.360 \longrightarrow 00:45:12.210$  It does factor it in but in a very crude way

 $934\ 00:45:12.210 \longrightarrow 00:45:14.280$  in the sense that the models have some settings  $935\ 00:45:14.280 \longrightarrow 00:45:18.360$  called like high malaria, low malaria or high HIV, low HIV.

936 00:45:18.360 --> 00:45:20.850 So depending on which country you're running it,

937 00:45:20.850 --> 00:45:24.120 you will set the setting to like high HIV country

 $938\ 00:45:24.120 \longrightarrow 00:45:26.550$  or low HIV country, the same for malaria,

 $939\ 00:45:26.550 \longrightarrow 00:45:29.640$  but it doesn't do anything beyond that,

940 00:45:29.640 --> 00:45:31.473 so only at a very close level.

941 00:45:34.350 --> 00:45:35.400 <v ->Causes of death or.</v>

942 00:45:36.870 --> 00:45:39.720 <v ->So the ICD-10 classification</v>

943 00:45:39.720 --> 00:45:42.480 will have around 30 plus causes of death

944 00:45:42.480 --> 00:45:44.070 for children's and neonates,

945 00:45:44.070 --> 00:45:45.753 I think much more for adults.

946 00:45:46.620 --> 00:45:48.420 There are no MITS for adults.

947 00:45:48.420 --> 00:45:50.700 MITS was only done for children's and neonates,

948 00:45:50.700 --> 00:45:53.343 only now adult MITS are being started,

 $949~00{:}45{:}54{.}330 \dashrightarrow 00{:}45{:}57{.}330$  but we have to kind of group them into broader categories

950 00:45:57.330 --> 00:45:58.980 because if you have 30 causes,

951 00:45:58.980 --> 00:46:01.500 your misclassification matrix will be 30 times 30.

952 00:46:01.500 --> 00:46:05.040 So we don't have the data to do estimation

953 00:46:05.040 --> 00:46:06.300 at that fine resolution.

 $954\ 00:46:06.300 \longrightarrow 00:46:08.220$  So we group them into broader categories.

 $955\ 00:46:08.220 \longrightarrow 00:46:10.950$  So seven for children, five for new neonates.

956 00:46:10.950 --> 00:46:13.770 <v ->Is one of the categories, I have no idea,</v>

957 00:46:13.770 --> 00:46:15.210 it is totally unknown.

958 00:46:15.210 --> 00:46:18.450 And if so, is that different from the uniform distribution

959 00:46:18.450 --> 00:46:20.373 across causes of death?

960 00:46:21.240 --> 00:46:22.680 <v ->That would be the uniform distribution.</v>

961 00:46:22.680 --> 00:46:24.810 There is no category which is, I have no idea,

962 00:46:24.810 --> 00:46:27.720 but it'll be probably reflected in a score that is very flat

963 00:46:27.720 --> 00:46:29.550 across the causes.

964 00:46:29.550 --> 00:46:32.040 <v ->If you think there are seven causes of death</v>

965 00:46:32.040 --> 00:46:33.540 and I'm working with the same dataset

966 00:46:33.540 --> 00:46:36.180 and I think there are 100 causes of death,

967 00:46:36.180 --> 00:46:39.420 will there be substantial differences in our marginal

 $968\ 00:46:39.420 \longrightarrow 00:46:41.340$  estimates of probability?

969 00:46:41.340 --> 00:46:44.820 Because our uniform posteriors

970 00:46:44.820 --> 00:46:48.030 place such different amounts of mass across the say

971 00:46:48.030 --> 00:46:50.820 30 versus 100 causes of death.

 $972\ 00:46:50.820 \longrightarrow 00:46:52.540 < v \longrightarrow Ves$ , there will be differences </v>

973 00:46:54.150 --> 00:46:58.380 and even when we are aggregating from the 30 causes

 $974~00{:}46{:}58{.}380 \dashrightarrow > 00{:}47{:}01{.}860$  to seven causes, the assumption is that within each category

 $975\ 00:47:01.860 \longrightarrow 00:47:03.930$  the misclassification rates are homogeneous

 $976\ 00:47:03.930 \longrightarrow 00:47:05.130$  within the finer category.

977 00:47:05.130 --> 00:47:07.860 So that is an assumption that we're working with.

 $978\ 00:47:07.860 \longrightarrow 00:47:09.910$  So definitely, there will be differences.

979 00:47:10.890 --> 00:47:11.723 <v ->Thank you.</v>

980 00:47:16.380 --> 00:47:18.630 <v ->I have one more question.</v>

981 00:47:21.690 --> 00:47:23.100 I'll ask a philosophical question

982 00:47:23.100 --> 00:47:23.933 if I may. <v ->Sure, yeah.</v>

983 00:47:23.933 --> 00:47:24.957 <v ->You commented,</v>

984 00:47:26.010 --> 00:47:27.180 I don't know, about halfway through,

985 00:47:27.180 --> 00:47:31.500 about how statisticians are working on a thing.

986 00:47:31.500 --> 00:47:34.020 Computer scientists are working on the same thing.

 $987\ 00:47:34.020 \longrightarrow 00:47:35.570$  There's a third group I forget.

988 00:47:37.320 --> 00:47:38.870 And nobody talks to each other.

989 00:47:39.930 --> 00:47:41.463 Now, many of us are,

 $990\ 00:47:42.330 \longrightarrow 00:47:43.580$  many of the students here

991 00:47:44.482 --> 00:47:47.032 are within the data science track of biostatistics.

 $992\ 00:47:48.660 \longrightarrow 00:47:50.523$  By the way, love your Twitter handle.

 $993\ 00:47:52.230 \longrightarrow 00:47:55.890$  But yeah, so how do we bridge those things

 $994\ 00:47:55.890 \longrightarrow 00:47:57.450$  that we take advantage of these things

995 00:47:57.450 --> 00:48:00.213 and it's not three separate versions of the same thing?

996 00:48:01.170 --> 00:48:04.320 <v ->I don't know if there's a systematic way.</v>

997 00:48:04.320 --> 00:48:07.530 H<br/>onestly, I came to know about much of the literature

 $998\ 00:48:07.530 \longrightarrow 00:48:08.550$  going through the revisions

 $999\ 00:48:08.550 \longrightarrow 00:48:10.680$  and one of the reviewer associate editors said

 $1000\ 00{:}48{:}10.680$  -->  $00{:}48{:}13.620$  there is a lot of work here in the econometrics literature,

 $1001 \ 00:48:13.620 \longrightarrow 00:48:14.760$  you should take a look.

 $1002 \ 00:48:14.760 \longrightarrow 00:48:15.720$  And that's kind of the value

1003 00:48:15.720 --> 00:48:17.490 of the peer review system I guess.

1004 00:48:17.490 --> 00:48:20.340 And so we looked at it and yes, there was a lot of work

 $1005\ 00:48:20.340 \longrightarrow 00:48:22.260$  and they just called it different things

1006 00:48:22.260 --> 00:48:23.250 and so I had no idea

1007 00:48:23.250 --> 00:48:25.800 when I was searching for that in the literature.

1008 00:48:25.800 --> 00:48:28.560 And we did see the Victor Chernozhukov paper

1009 00:48:28.560 --> 00:48:30.150 I think is in "Journal of Economics,"

1010 00:48:30.150 --> 00:48:32.610 but it's basically an asymptotic statistics paper.

 $1011\ 00:48:32.610$  --> 00:48:35.640 It kind of shows that these generalized Bayes stuff,

1012 00:48:35.640 --> 00:48:38.400 which they call as Laplace-type estimators,

 $1013\ 00:48:38.400 \longrightarrow 00:48:39.990$  has all these nice properties

1014 00:48:39.990 --> 00:48:42.140 that a standard vision posterior will have.

1015 00:48:43.200 --> 00:48:46.410 But yeah, I think talking to more people

1016 00:48:46.410 --> 00:48:48.930 and like interacting and telling about your work

1017 00:48:48.930 --> 00:48:49.763 will kind of,

1018 00:48:49.763 --> 00:48:52.320 and someone will say that, oh yeah, I do something similar.

 $1019\ 00:48:52.320 \longrightarrow 00:48:54.600$  You should look at this paper,

1020 00:48:54.600 --> 00:48:56.754 it's probably. <br/> <v ->Hopefully Twitter helps.</br/>/v>

1021 00:48:56.754 --> 00:48:57.587 <v ->Sorry?</v>

1022 00:48:57.587 --> 00:48:58.420 <v ->Hopefully Twitter helps.</v>

 $1023 \ 00:48:58.420 \longrightarrow 00:49:00.300 < v \longrightarrow Yeah, yeah, definitely. </v>$ 

 $1024 \ 00:49:00.300 \longrightarrow 00:49:02.340$  Engagement through any like in-person

1025 00:49:02.340 --> 00:49:05.463 or social media platform would be useful, yeah.

 $1026\ 00:49:07.530 \longrightarrow 00:49:08.460 < v \longrightarrow All right, well thanks so much. </v>$ 

1027 00:49:08.460 --> 00:49:11.679 I think we're out of time so we'll stop it there.

 $1028\ 00:49:11.679 \longrightarrow 00:49:14.790$  (attendant muttering indistinctly)

 $1029 \ 00:49:14.790 \longrightarrow 00:49:16.590$  Hope everybody has a wonderful fall break.

1030 00:49:16.590 --> 00:49:17.640 See you next week.

1031 00:49:19.167 --> 00:49:23.584 (attendants chattering indistinctly)

 $1032\ 00:49:36.727 \longrightarrow 00:49:37.923 < v \text{ Learner}$ The other organizer. </v>

 $1033\ 00:49:37.923 \longrightarrow 00:49:39.398$  (learner muttering indistinctly)

1034 00:49:39.398 --> 00:49:43.815 (attendants chattering indistinctly)

1035 00:49:52.604 --> 00:49:54.760 <v ->Or may<br/>be because they're susceptible.</v>

 $1036\ 00:49:54.760 \longrightarrow 00:49:59.177$  (attendants chattering indistinctly)

1037 00:50:04.226 --> 00:50:06.327 <v ->Thank you. Anyone else need to sign in?</v>

1038 00:50:06.327 --> 00:50:10.744 (attendants chattering indistinctly)

1039 00:50:19.104 --> 00:50:20.966 <v ->Infection but they're also premature babies.</v>

1040 00:50:20.966 --> 00:50:25.383 (attendants chattering indistinctly)

1041 00:50:30.104 --> 00:50:31.890 < v -> Premature, but also it's that </v>

1042 00:50:31.890 --> 00:50:33.506 it's not a distinct.

 $1043 \ 00:50:33.506 \longrightarrow 00:50:35.160$  (attendants chattering indistinctly)

1044 00:50:35.160 --> 00:50:38.070 <v ->Cause of death is very blurry in this day.</v>

 $1045 \ 00:50:38.070 \longrightarrow 00:50:40.414 < v \longrightarrow Is that part of why like. </v>$ 

 $1046\ 00:50:40.414 \longrightarrow 00:50:44.831$  (attendants chattering indistinctly)

1047 00:50:46.157 --> 00:50:48.057 <v ->'Cause a symptom given cause session</v>

 $1048 \ 00:50:49.011 \longrightarrow 00:50:50.520$  with that much of variation across country.

 $1049\ 00:50:50.520 \longrightarrow 00:50:51.548 < v \text{ Learner} > Cause. < / v > 00:50:50.520 \longrightarrow 00:50:51.548 < v \text{ Learner} > Cause. < / v > 00:50:50.520 \longrightarrow 00:50:51.548 < v \text{ Learner} > Cause. < / v > 00:50:50.520 \longrightarrow 00:50:51.548 < v \text{ Learner} > Cause. < / v > 00:50:50.520 \longrightarrow 00:50:50.520 \longrightarrow 00:50:51.548 < v \text{ Learner} > Cause. < / v > 00:50:50.520 \longrightarrow 00:50.520 \longrightarrow 00:500 \longrightarrow 00:5000 \longrightarrow 00:5000 \longrightarrow 00:500 \longrightarrow 00:5000 \longrightarrow 00:5000 \longrightarrow 00:50000 \longrightarrow$ 

 $1050\ 00:50:51.548 \longrightarrow 00:50:52.645$  (learner muttering indistinctly)

1051 00:50:52.645 --> 00:50:53.790 Cause.

1052 00:50:53.790 --> 00:50:57.614 <v ->Reporting depends on who is answering.</v>

1053 00:50:57.614 --> 00:51:02.031 (attendants chattering indistinctly)

1054 00:51:03.810 --> 00:51:05.400 <v ->You need to go next.</v>

1055 00:51:05.400 --> 00:51:06.233 <v ->Back to.</v>

1056 00:51:09.026 --> 00:51:10.347 <v ->I guess, yeah.</v>

 $1057 \ 00:51:10.347 \longrightarrow 00:51:11.795$  You need one of us to let you.

1058 00:51:11.795 --> 00:51:14.062 (lecturer muttering indistinctly)

 $1059\ 00:51:14.062 \longrightarrow 00:51:15.929 < v \longrightarrow It might be a short answer. </v>$ 

 $1060 \ 00:51:15.929 \longrightarrow 00:51:16.762$  Yeah, and it's short answer.

1061 00:51:16.762 --> 00:51:20.030 (attendants chattering indistinctly)

1062 00:51:20.030 --> 00:51:22.216 <v ->I don't have to, will you? (laughs)</v>
